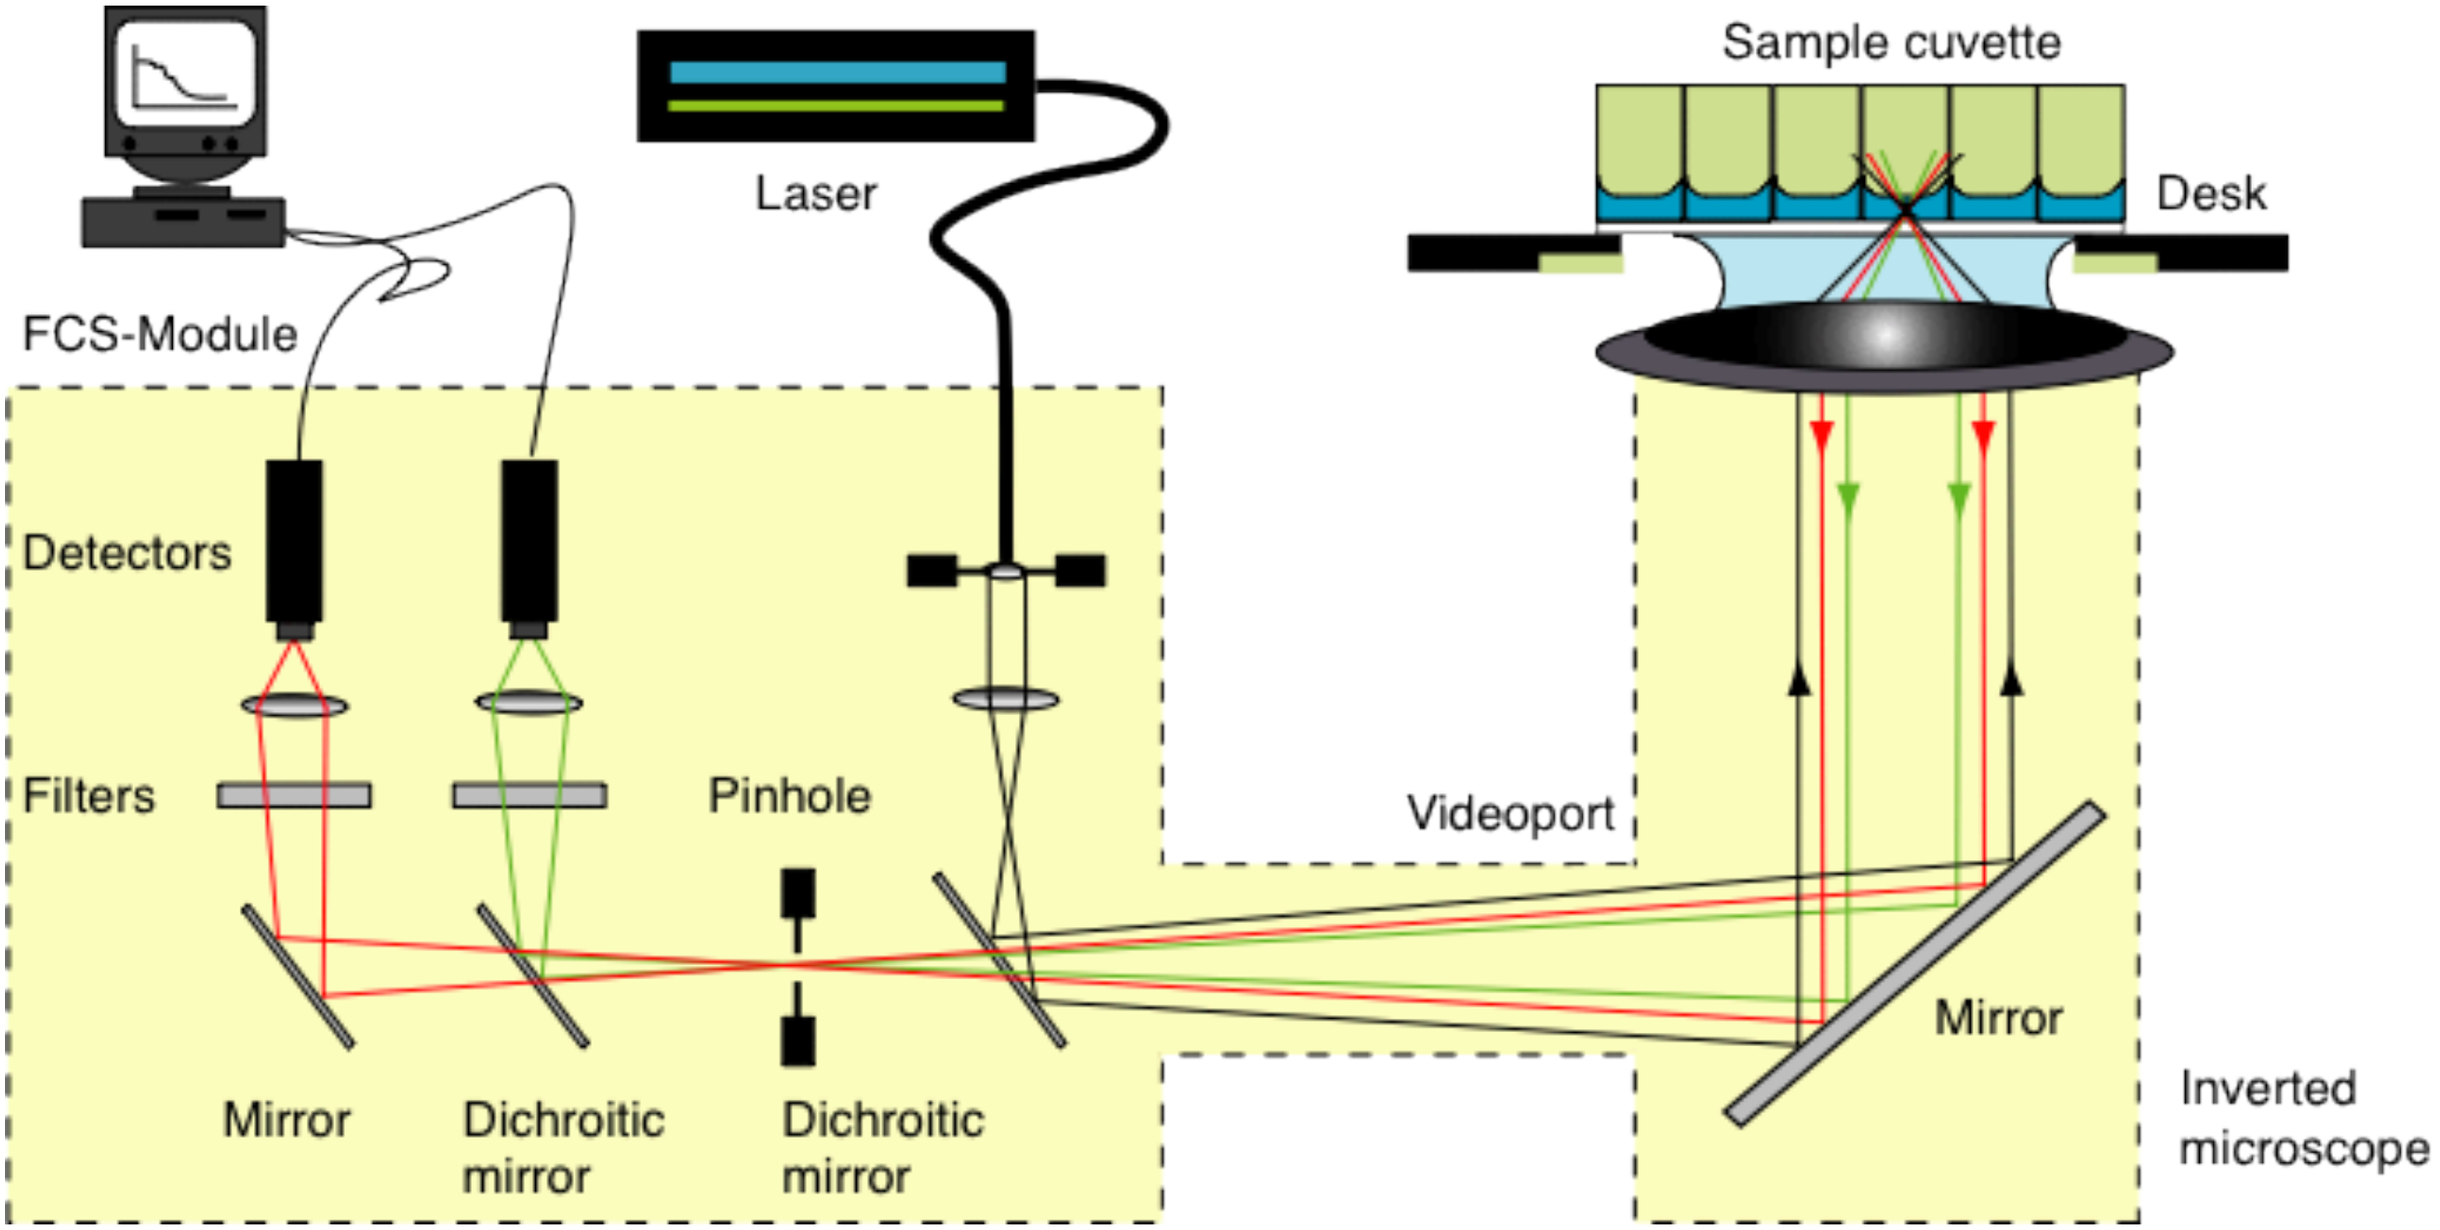
Fluorescence fluctuation microscopy: FRAP and FCS

Confocal laser scanning fluorescence microscope for the mobility analysis in living cells

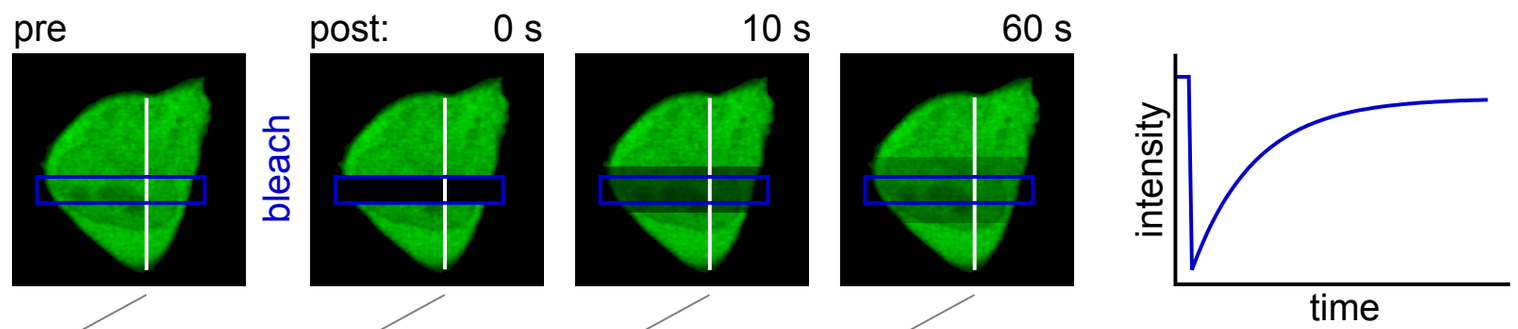


Ensemble measurements of protein mobility and interactions

spatial/temporal resolution

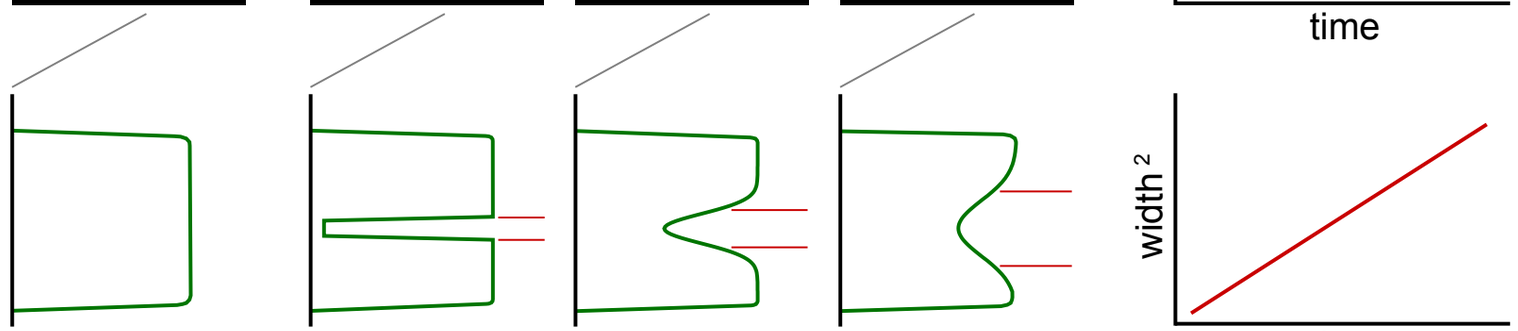
bleach once

FRAP intensity



1 µm
100 ms - hours

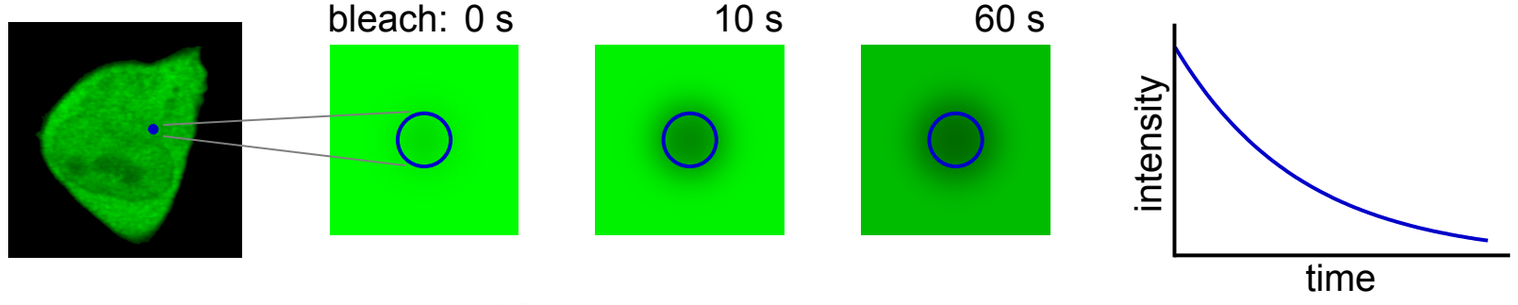
FRAP spatial analysis



10 µm
100 ms - hours

continue bleach

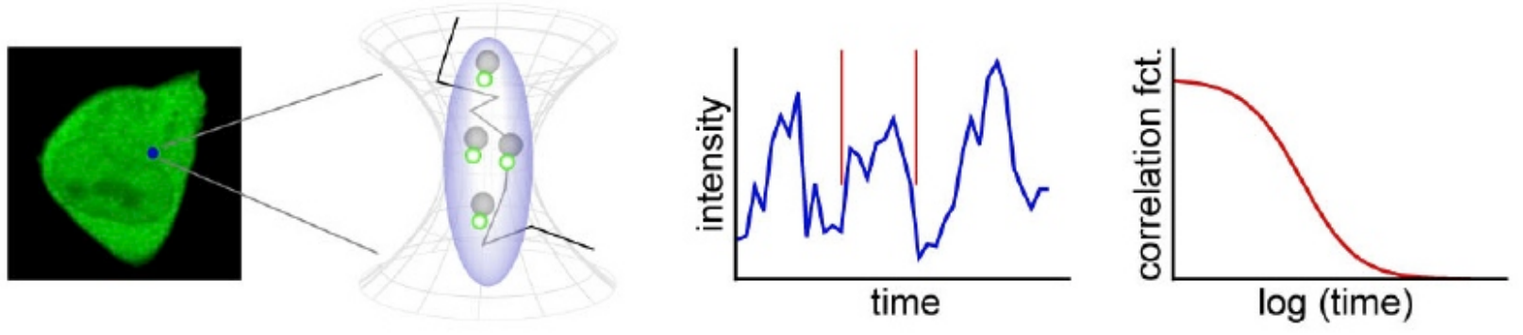
CP/ FLIP



1 µm
100 ms - hours

correlate

FCS



0.3 µm
10 µs - 1 s

Wachsmuth, M., Caudron-Herger, M. and Rippe, K. (2008). *Biochim. Biophys. Acta* **1783**, 2061-2079.

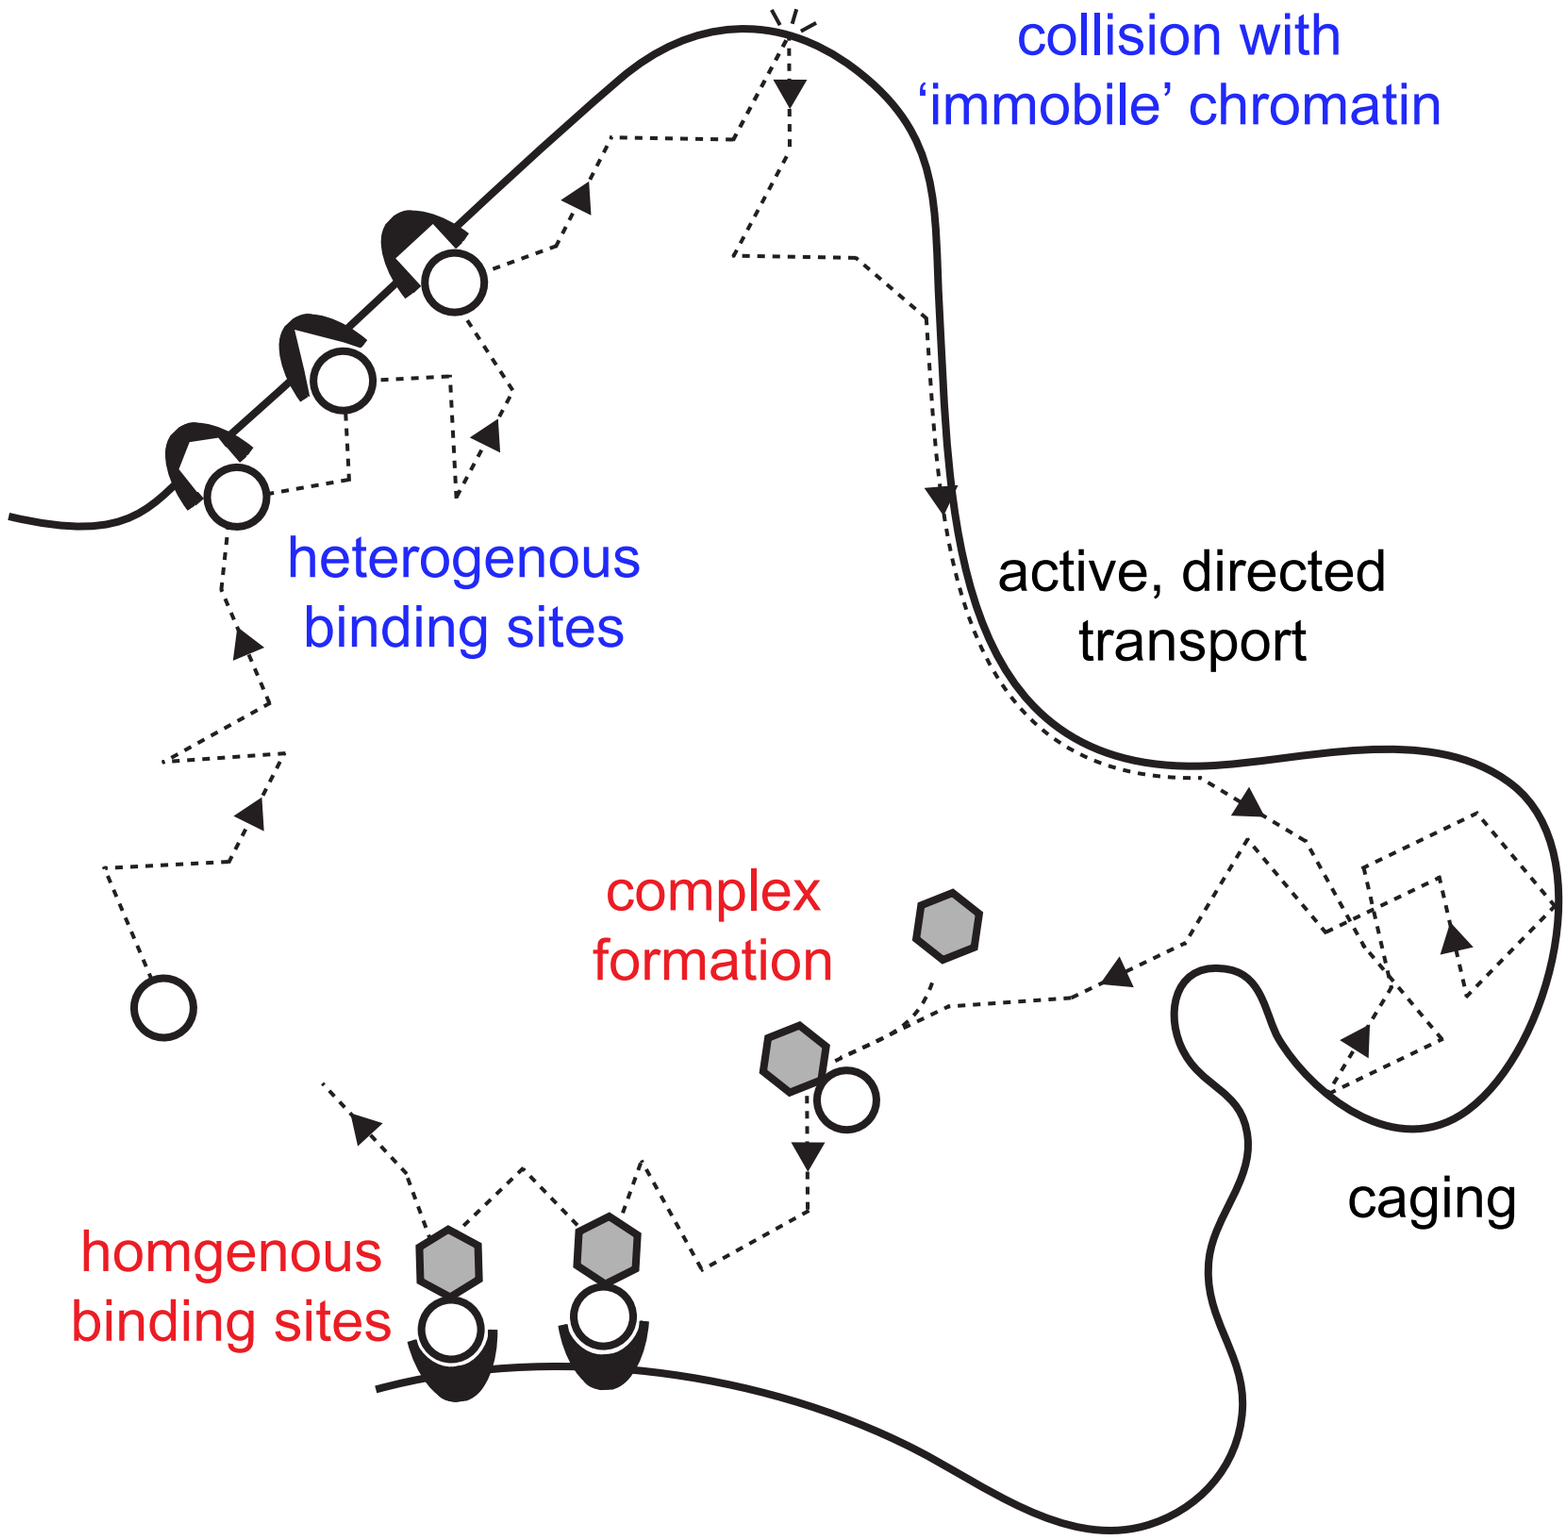
Methods comparison

FRAP (for slow/immobile particles, ~100 ms time resolution)
- diffusion coefficients
- rate constants (at immobile substrates)
- immobile fractions
- photoactivation instead of bleaching (k_{off} measurements)

CP/FLIP (for faster particles)
- dissociation rate (at immobile substrates)

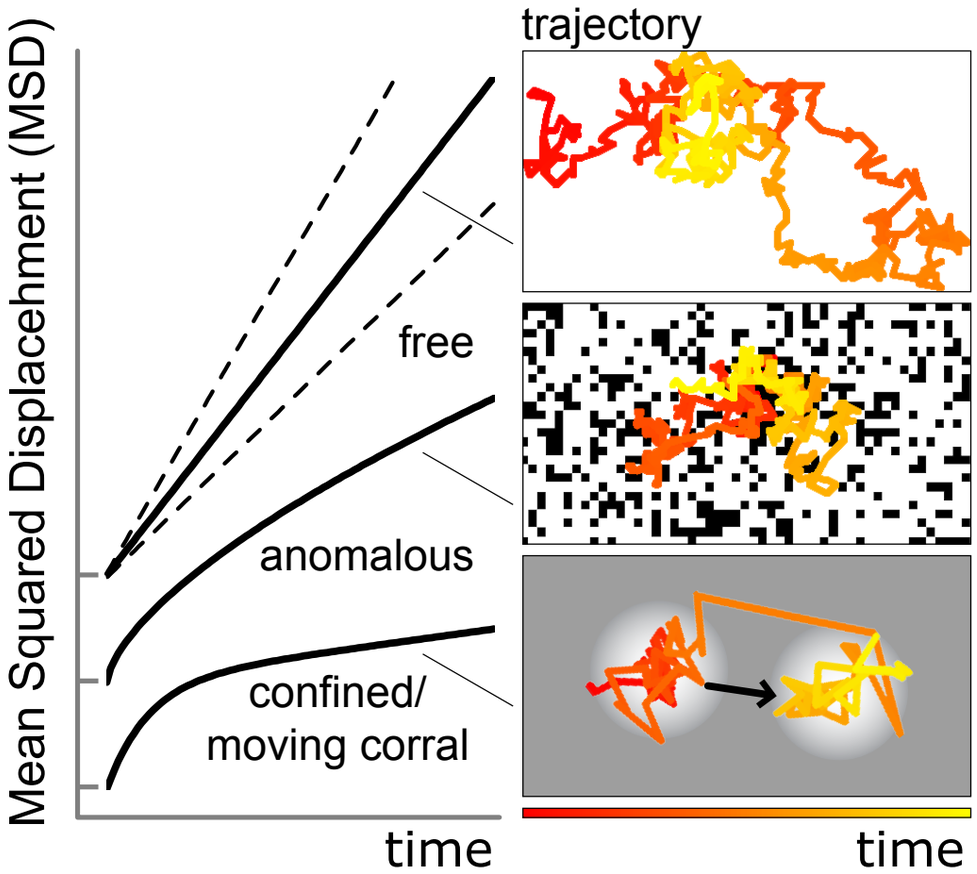
FCS (for fast particles, µs time resolution)
- diffusion coefficients
- rate constants (at mobile substrates)
- anomaly parameters
- concentrations

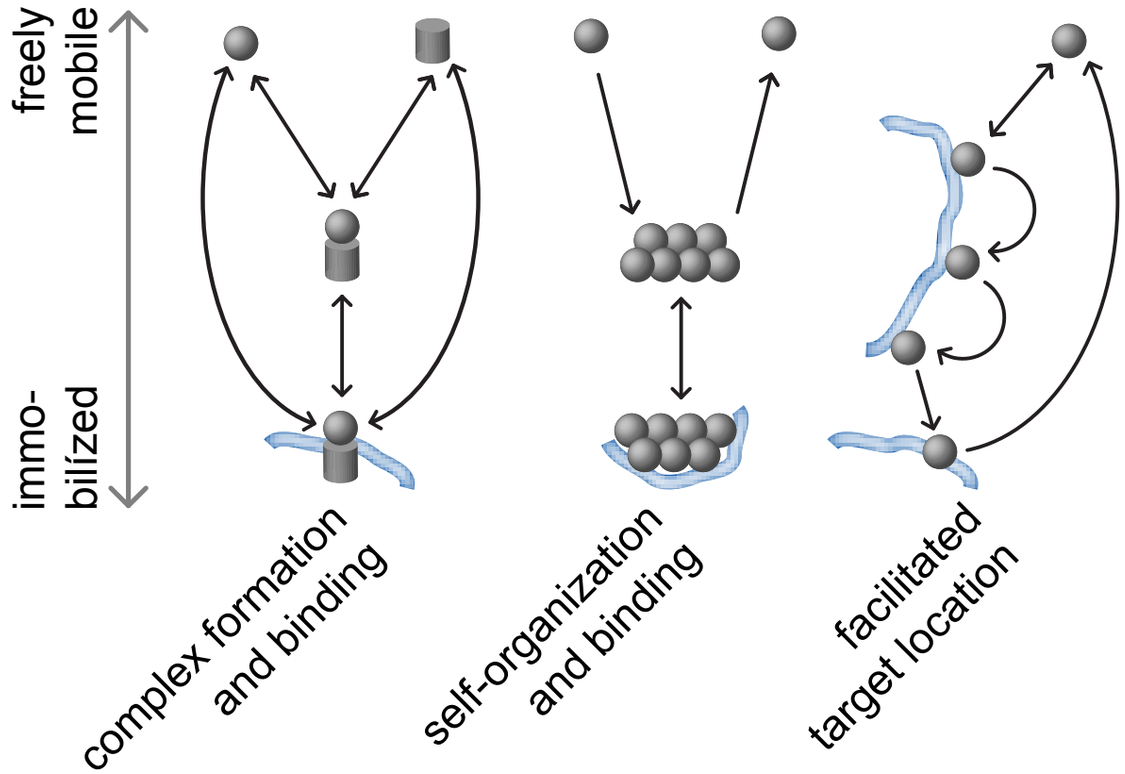
The problem: many things affect the observed mobility



Protein mobility and interactions in the cell

$$MSD = 6\,D\,t^{\alpha}$$





Dependence of diffusion coefficient D and molecular mass *M*

protein: $D \propto M^{-\frac{1}{3}}$ DNA: $D \propto M^{-\frac{1}{2}}$

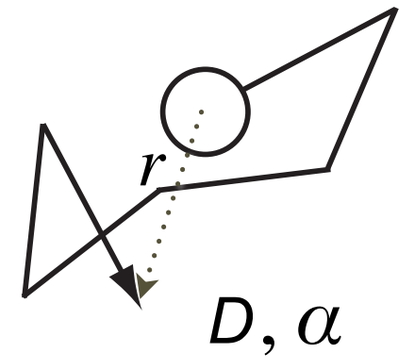
double mass *M* => 0.8 fold lower *D* double mass *M* => 0.7 fold lower *D*

Wachsmuth, M., Caudron-Herger, M. and Rippe, K. (2008). *Biochim. Biophys. Acta* **1783**, 2061-2079.

Determining diffusion coefficient D, kinetic binding rates k_{on} and k_{off}, and the apparent equilibrium constant K_{eq}^*

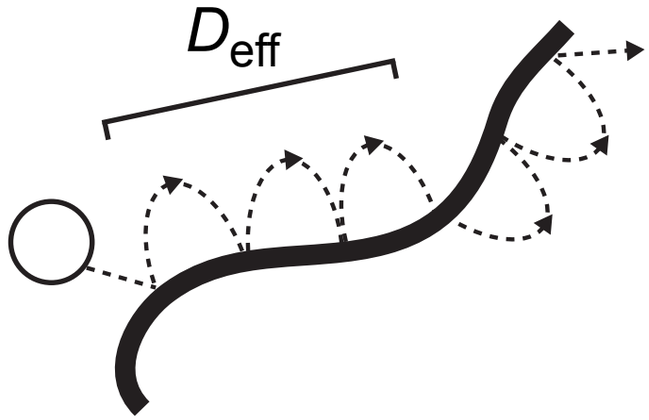
diffusion without binding,

α = 1 for free diffusion



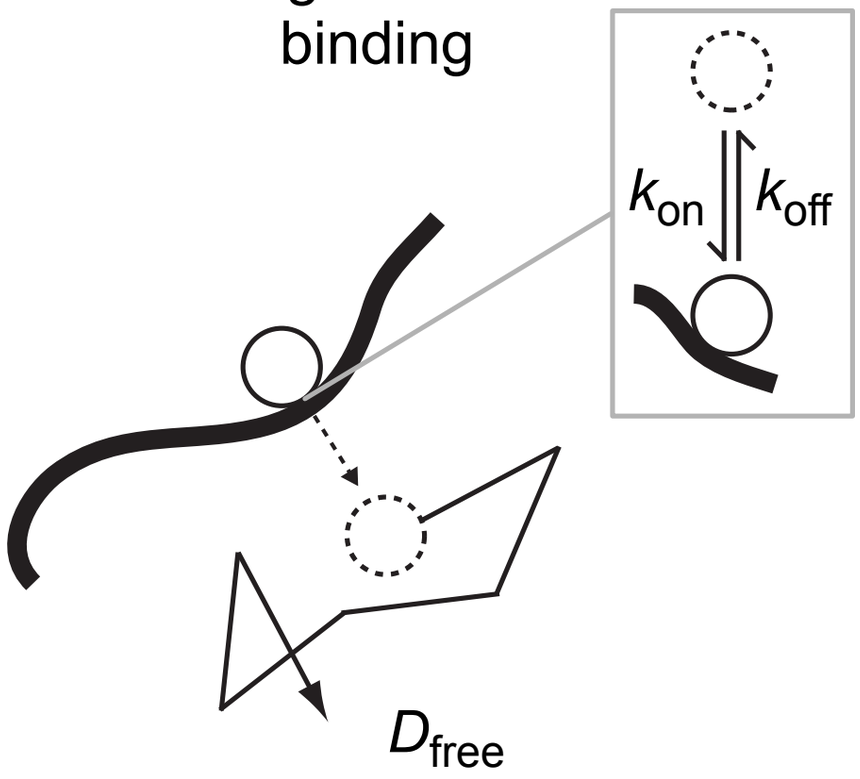
$$\left\langle r^2 \right\rangle = 6 \cdot D \cdot t^{\alpha}$$

transient chromatin binding



$$D_{\text{eff}} = \frac{D}{1 + K_{\text{eq}}^*}$$

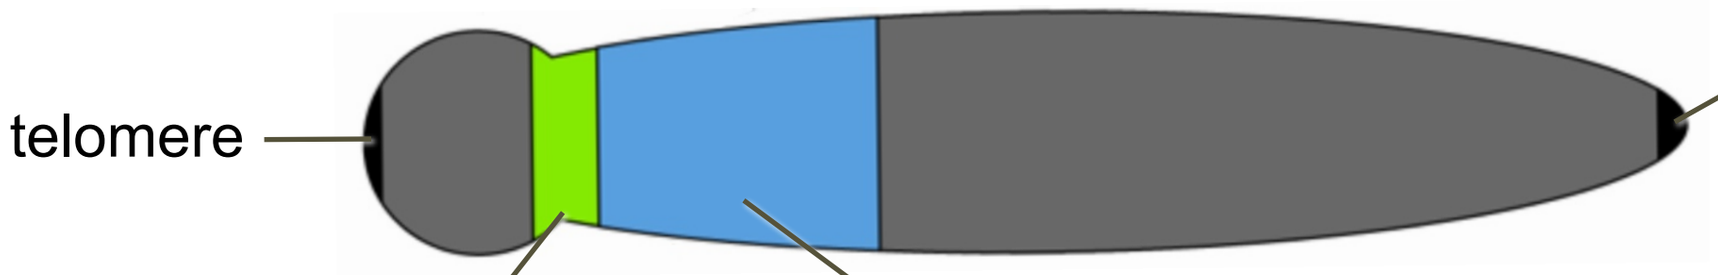
strong chromatin binding



$$K_{\text{eq}}^* = \frac{k_{\text{on}}^*}{k_{\text{off}}} = \frac{k_{\text{on}} \cdot [S]_{\text{eq}}}{k_{\text{off}}}$$

Erdel, Müller-Ott, Baum, Wachsmuth & Rippe (2011) *Chromosome Res* **19**, 99–115.

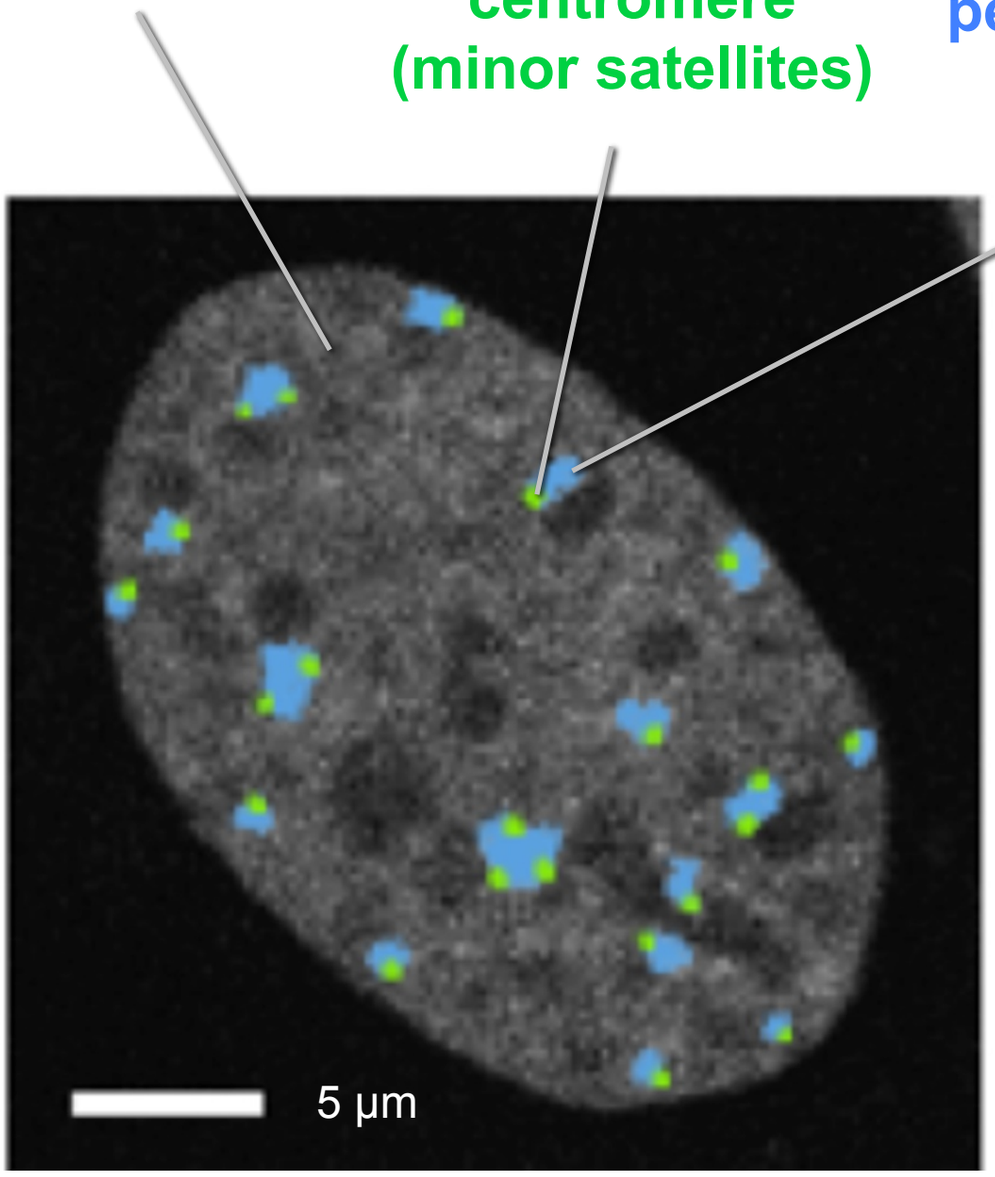
Pericentric heterochromatin (PCH) in mouse cells



“euchromatin”

centromere (minor satellites)

pericentric heterochromatin (PCH) (major satellites repeats)



Mouse pericentric heterochromatin

- “chromocenters” visualized by DAPI staining
- 5meC, H3K9me3, H4K20me3
- HP1, Suv39h, Suv4-20h
- silences transcription of repeats (requires Suv39h)
- important for chromosome segregation

Specificity, propagation and epigenetic memory?

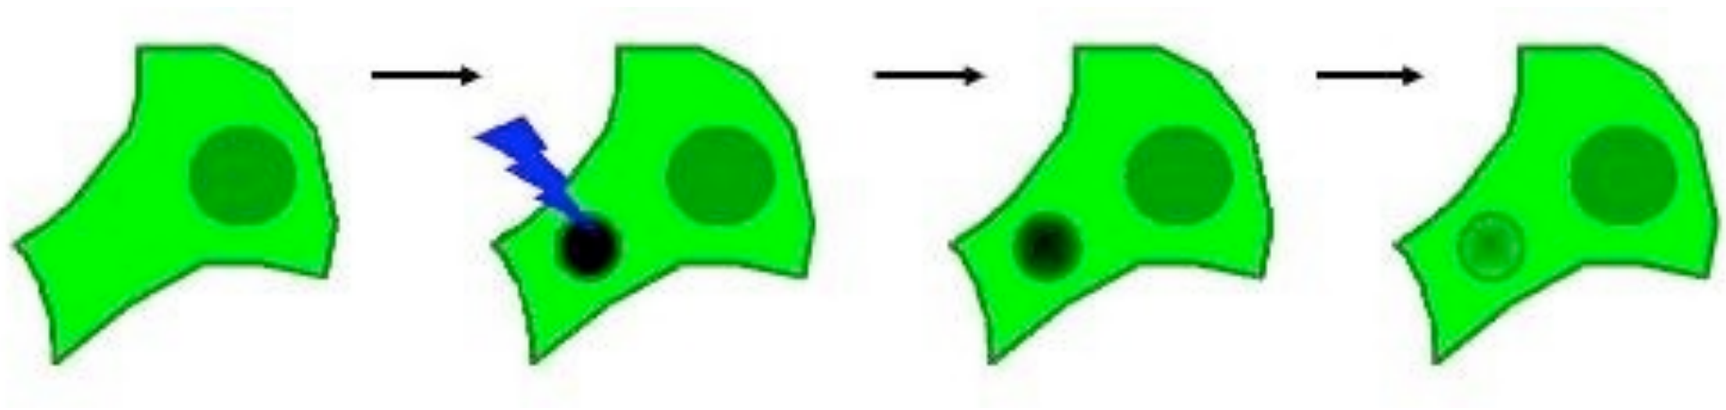
Fluorescence Recovery After Photobleaching (FRAP)

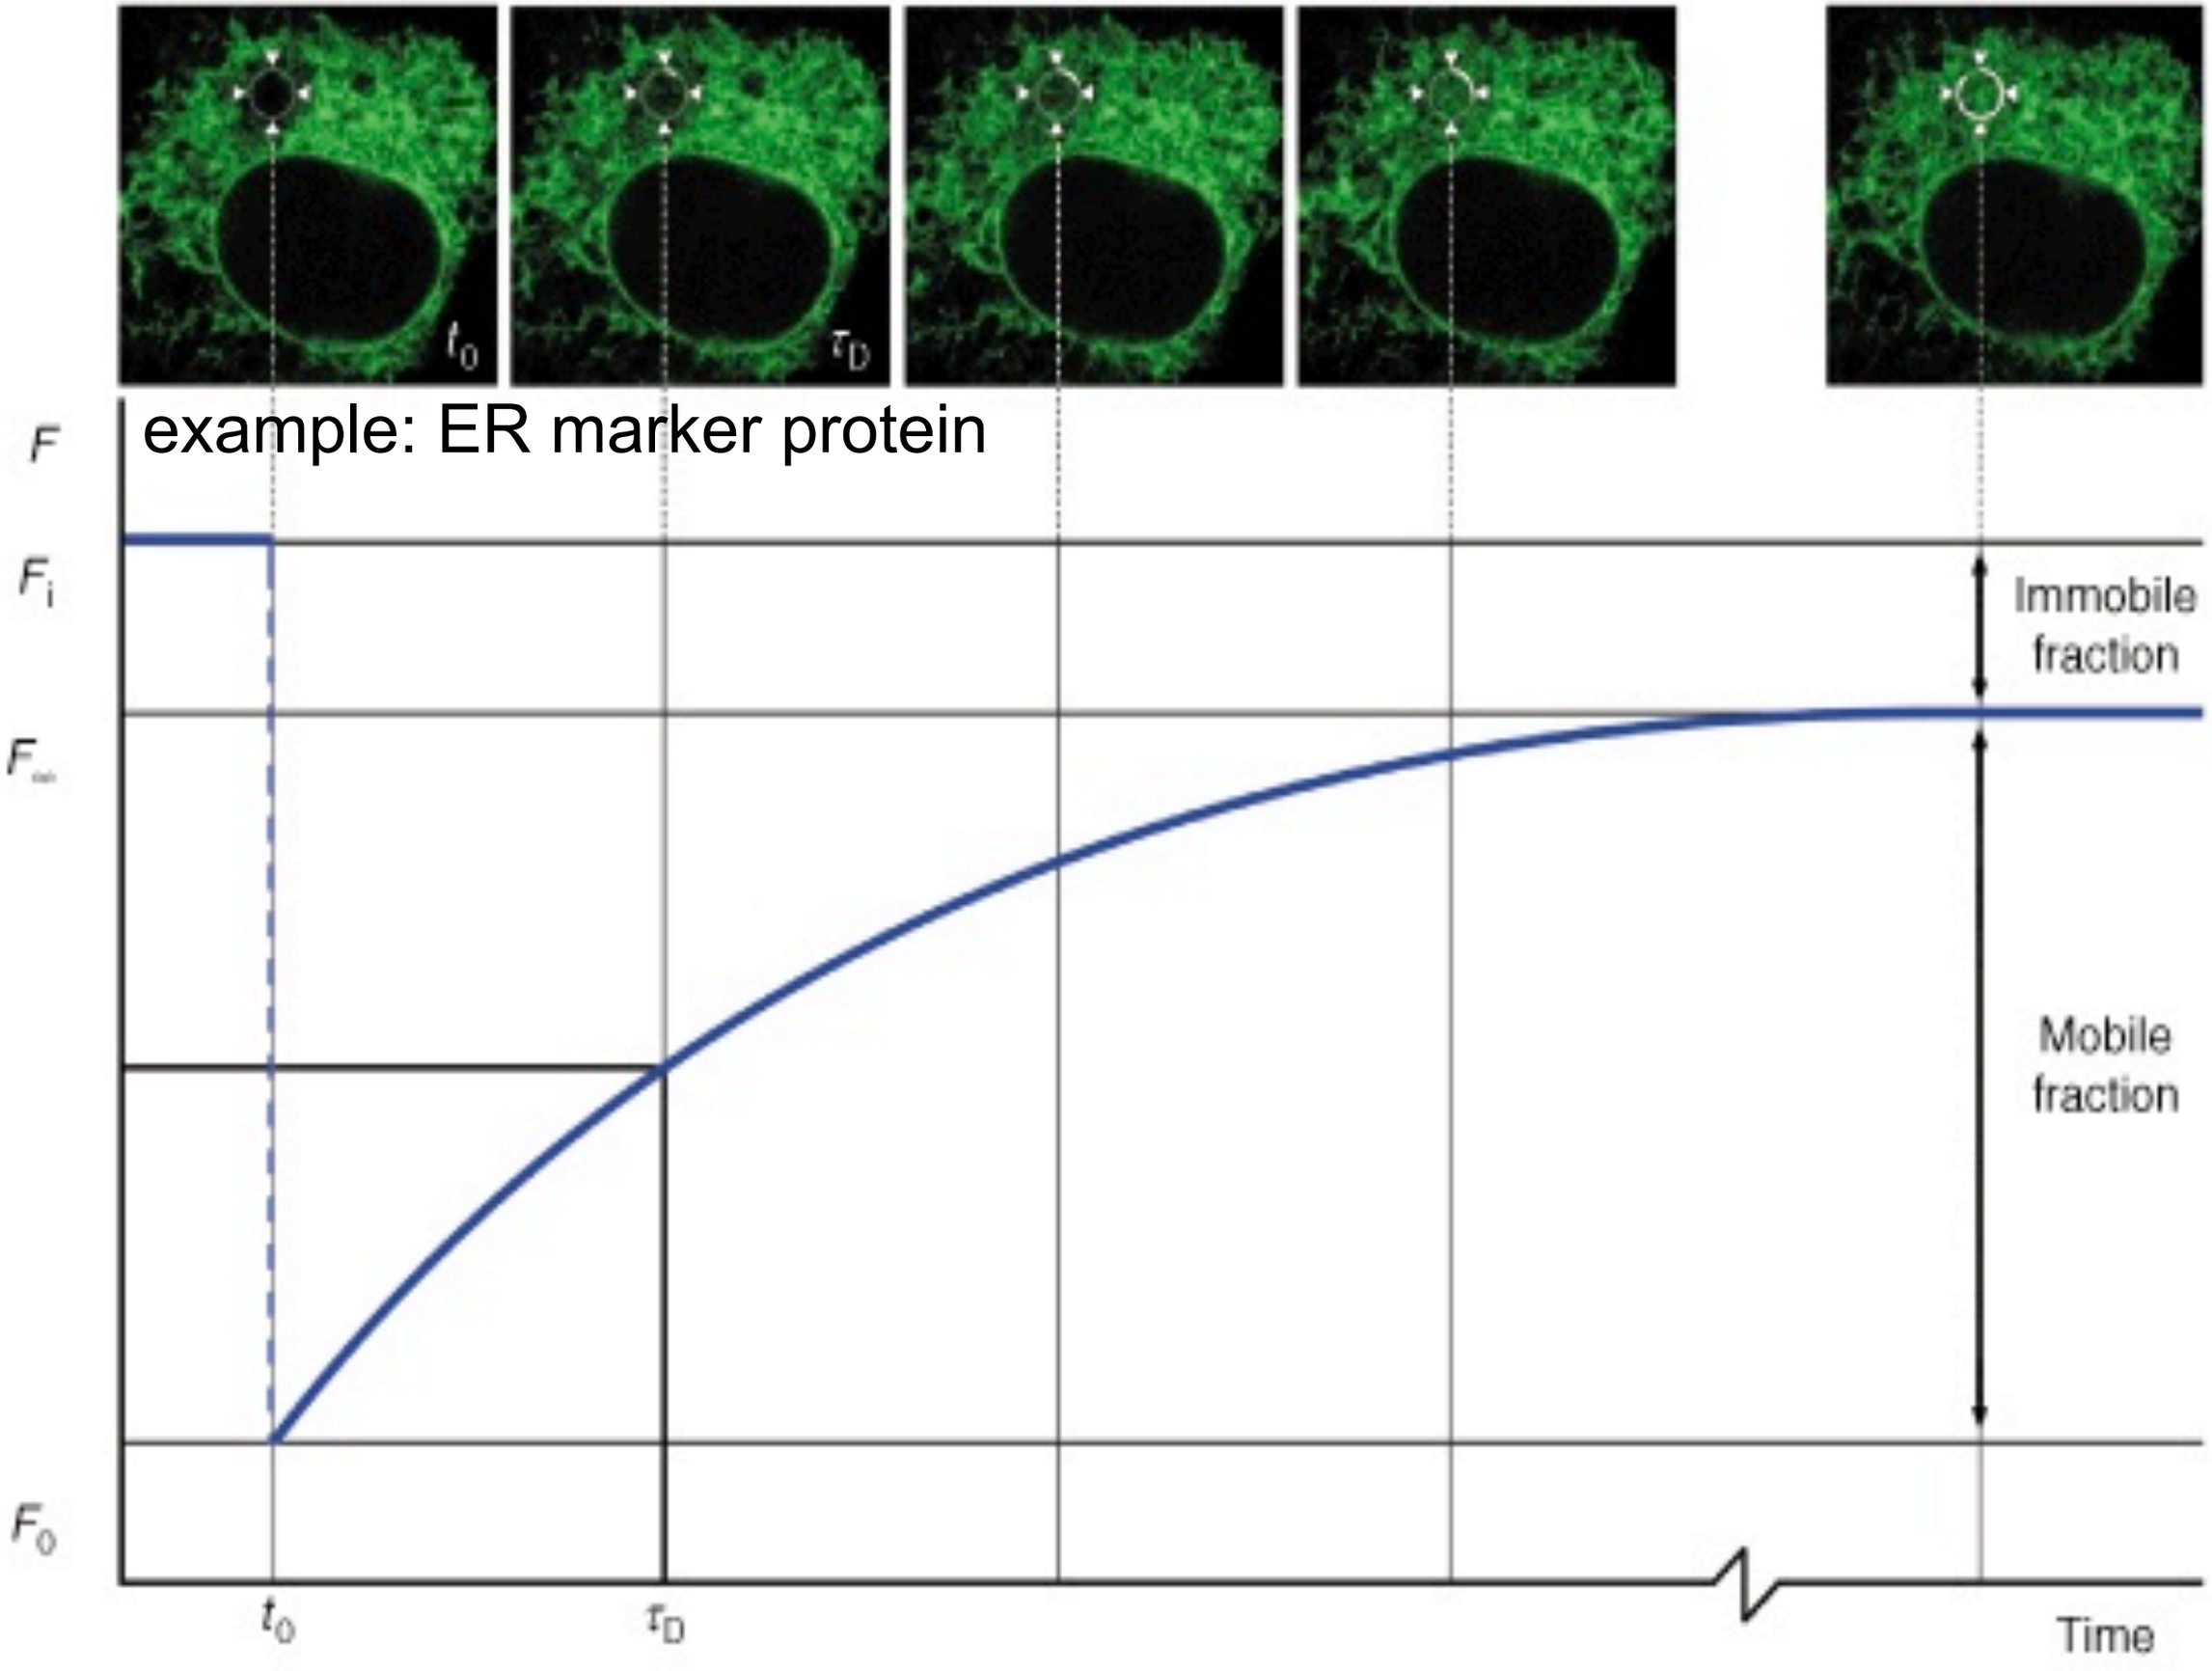
Fluorescence Recovery After Photobleaching (FRAP)

Protocol:

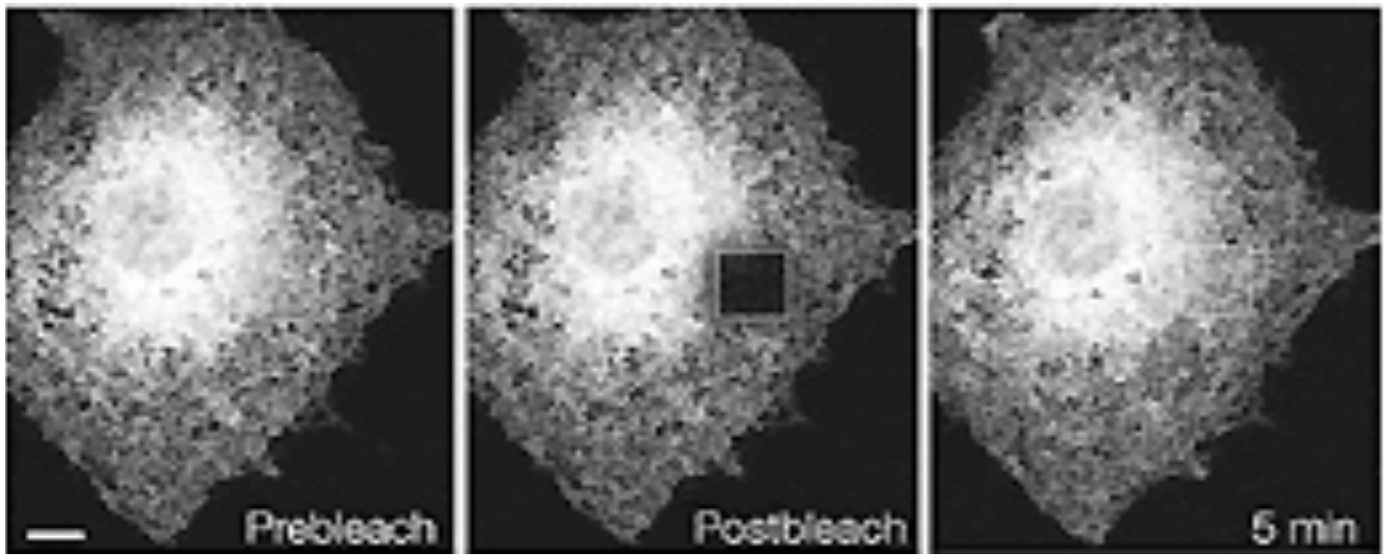
1. Bleach particles (with a laser)
2. Wait and watch during they diffuse away
3. Fit the fluorescence-over-time curve or profile

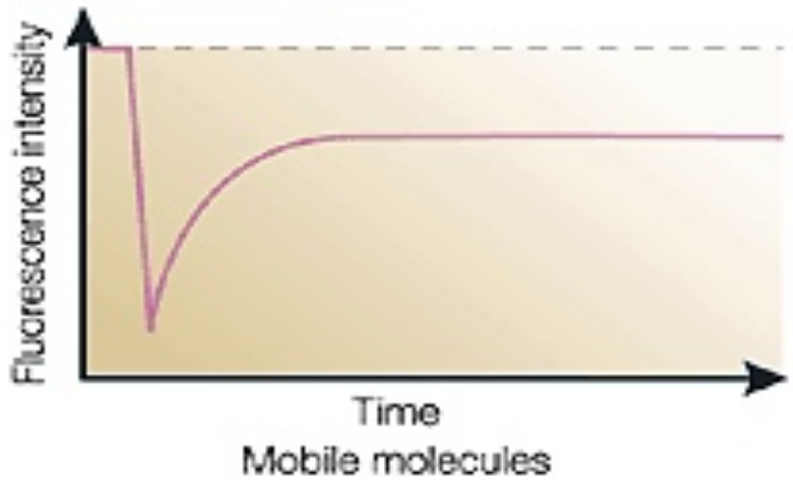


Source: Wikipedia

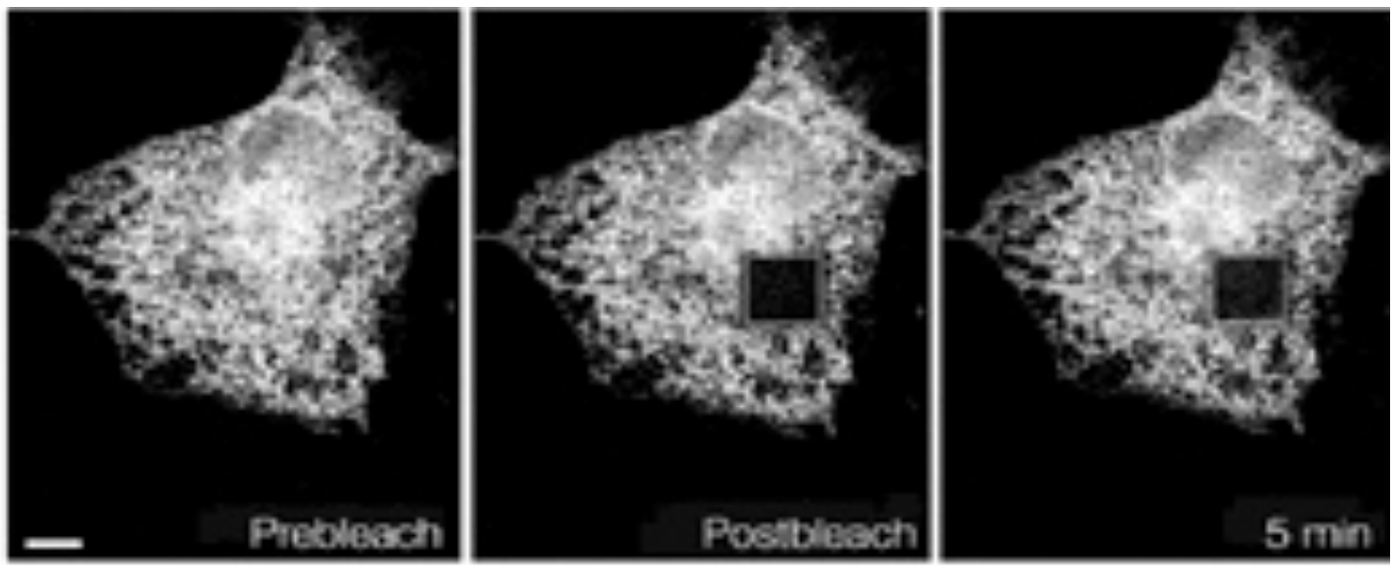


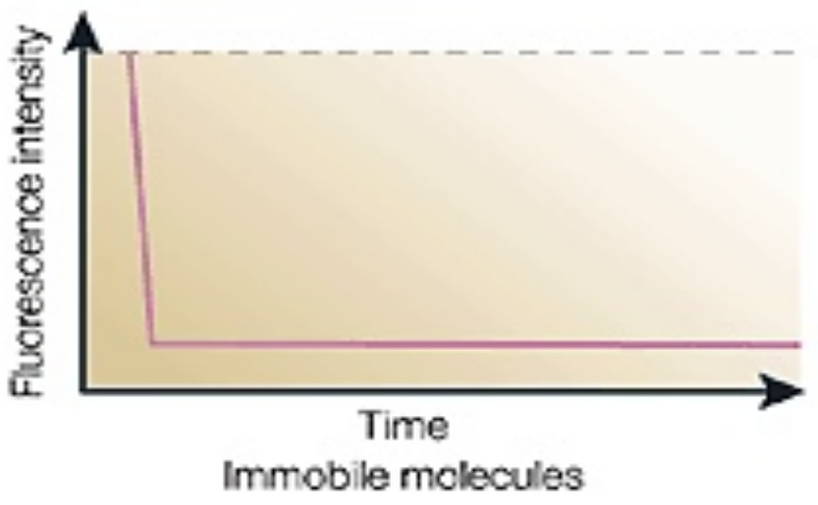
Reits et al. 2001 (From fixed to FRAP: measuring protein mobility and activity in living cells)





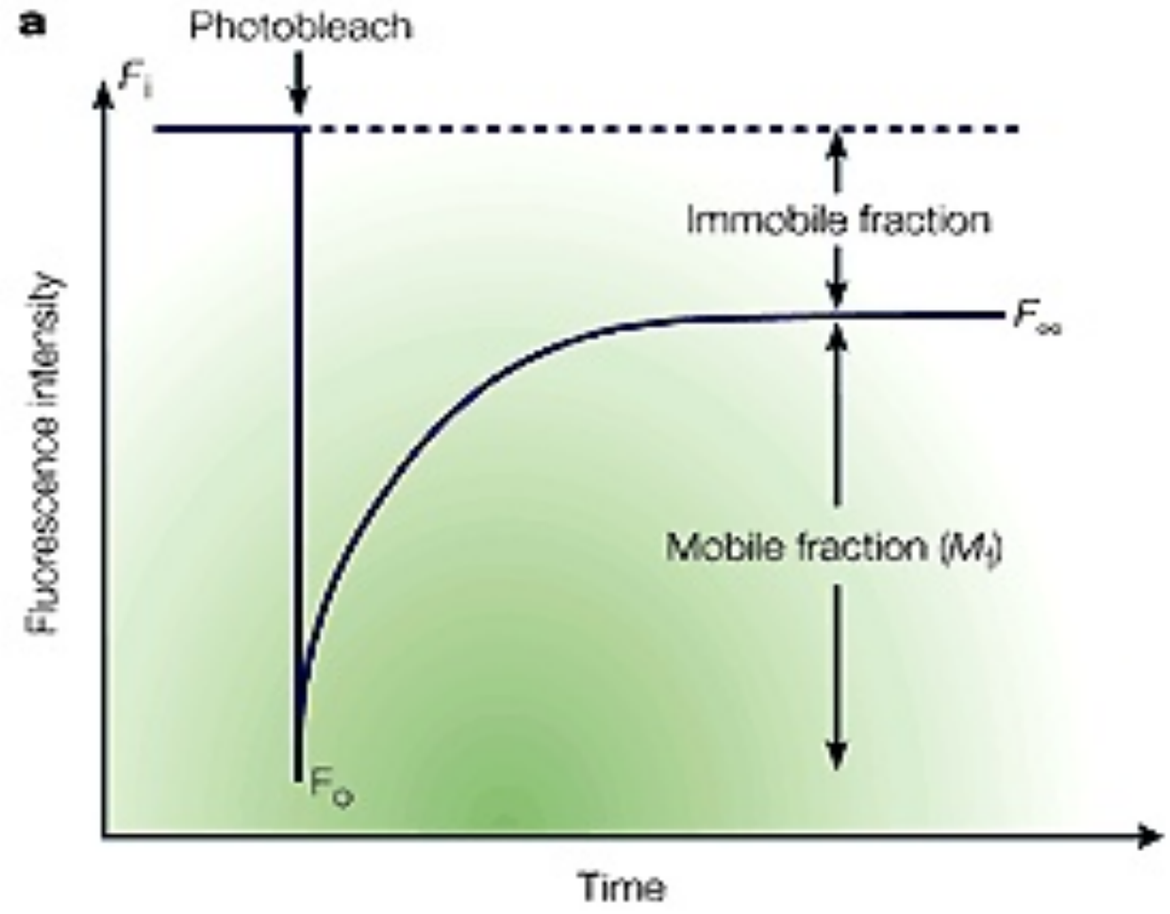
mobile protein





immobile protein

Typical FRAP curve



F_i: f.i. before bleaching
F_0: f.i. just after bleaching
F_∞: f.i. in recovery region

mobile fraction $M_f = \frac{F_\infty - F_0}{F_i - F_0}$

characteristic diffusion time $\tau_D = \frac{w^2}{4D}$

bleach radius w
diffusion coefficient D

Equation for the recovery curve in the absence of binding:

$$F_i(t) = e^{-\frac{2\tau_D}{t}}\left[I_0\left(\frac{2\tau_D}{t}\right) + I_1\left(\frac{2\tau_D}{t}\right)\right]$$

I_0, I_1: Modified Bessel functions

FRAP with fast binding

Fast binding: Reduction of the diffusion coefficient, **shape** of the curve remains **unchanged**

„Fast“ means: Many binding events occur during translocations on the length scale of the bleach spot

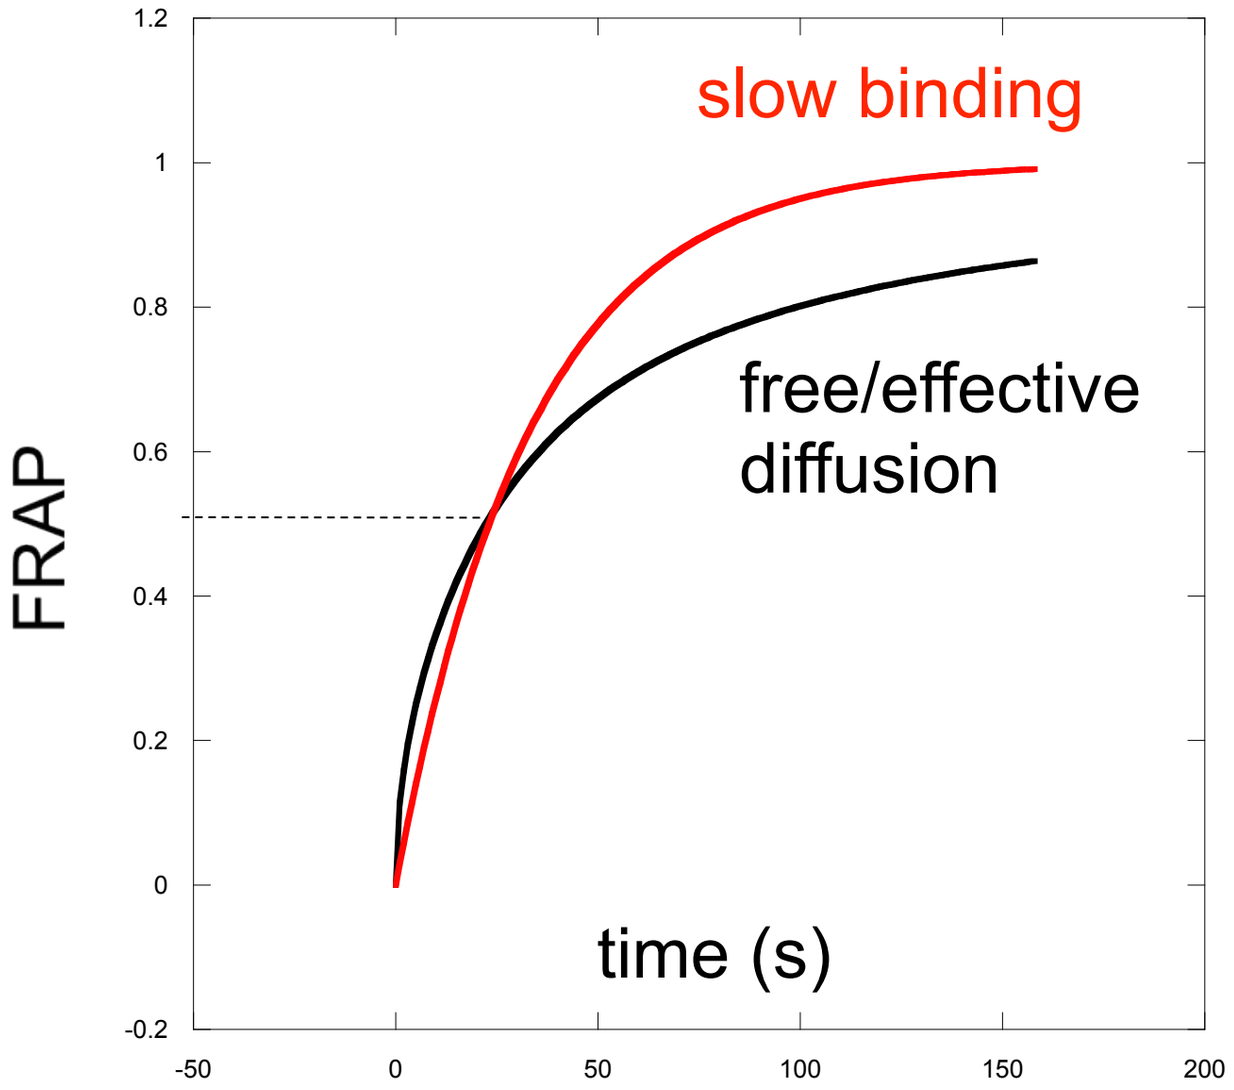
Only one fit parameter: Effective diffusion coefficient

$$D_{\mathrm{eff}} = \frac{D}{1 + \dfrac{k^{*}_{\mathrm{on}}}{k_{\mathrm{off}}}}$$

If *D* is known, the ratio of the rate constants is obtained

FRAP with slow binding

Long-lived binding events lead to different shape of recovery curve



Effective diffusion (no or fast binding):

$$F_{\mathrm{i}}(t) = e^{-\frac{2\tau_D}{t}}\left[I_0\left(\frac{2\tau_D}{t}\right) + I_1\left(\frac{2\tau_D}{t}\right)\right]$$

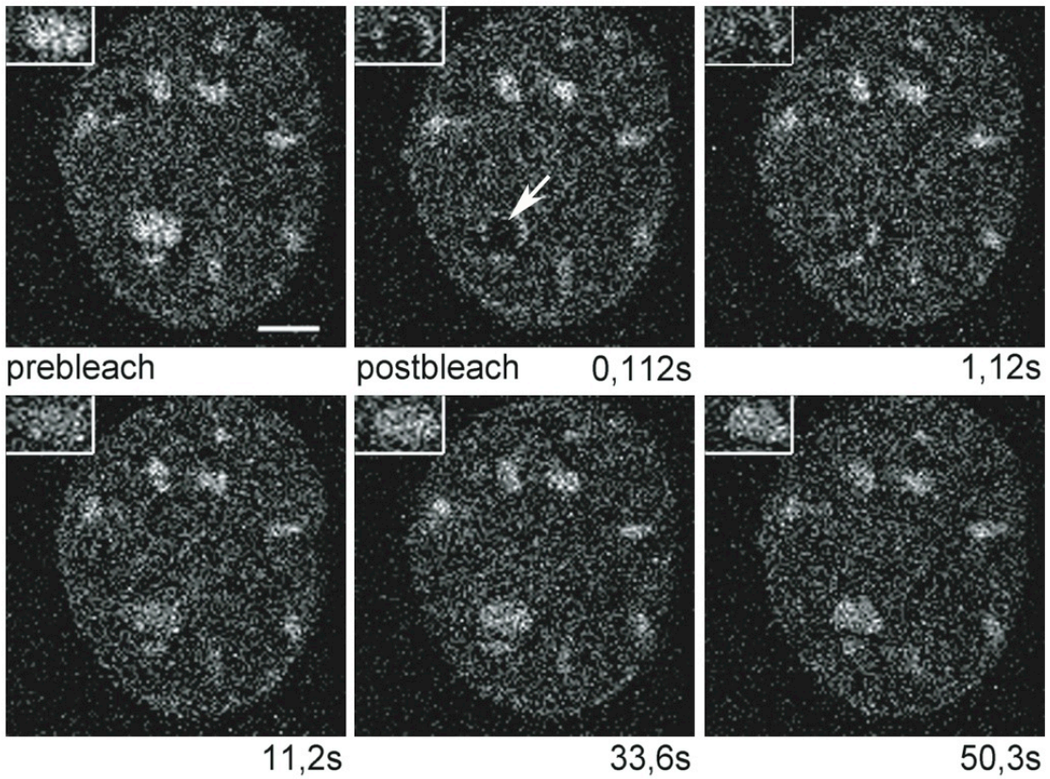
Slow binding:

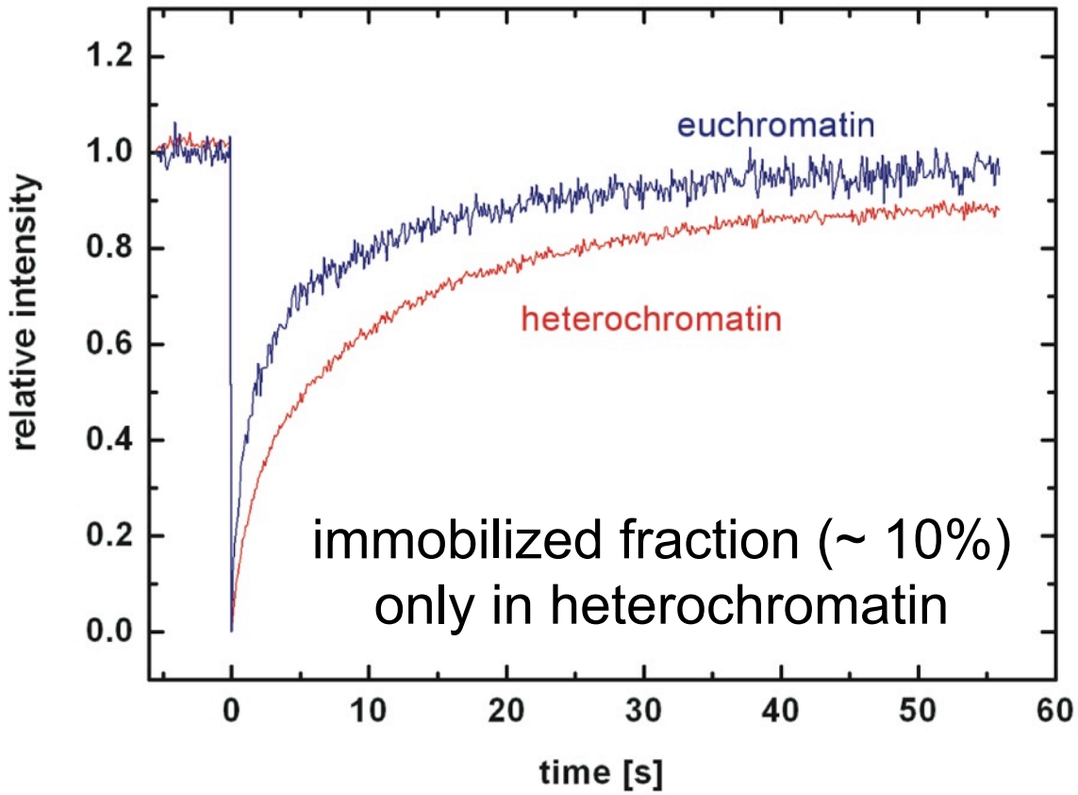
$$F_{\mathrm{i}}(t) = 1 - e^{-k_{\mathrm{off}} t}$$

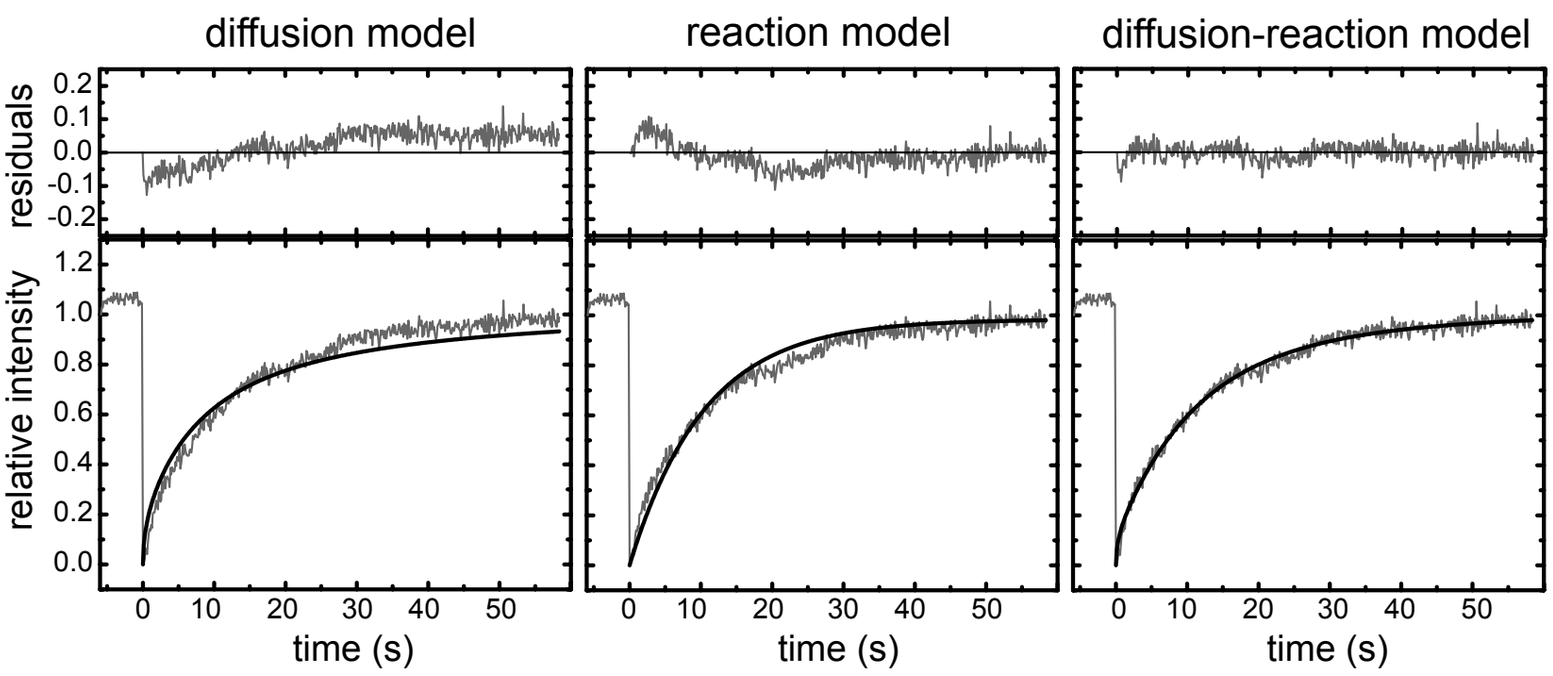
k_{off}: dissociation rate

Moderately fast binding: no analytical solution

Intensity analysis FRAP resolves HP1 diffusion and interactions on the 1 µm and second time scale

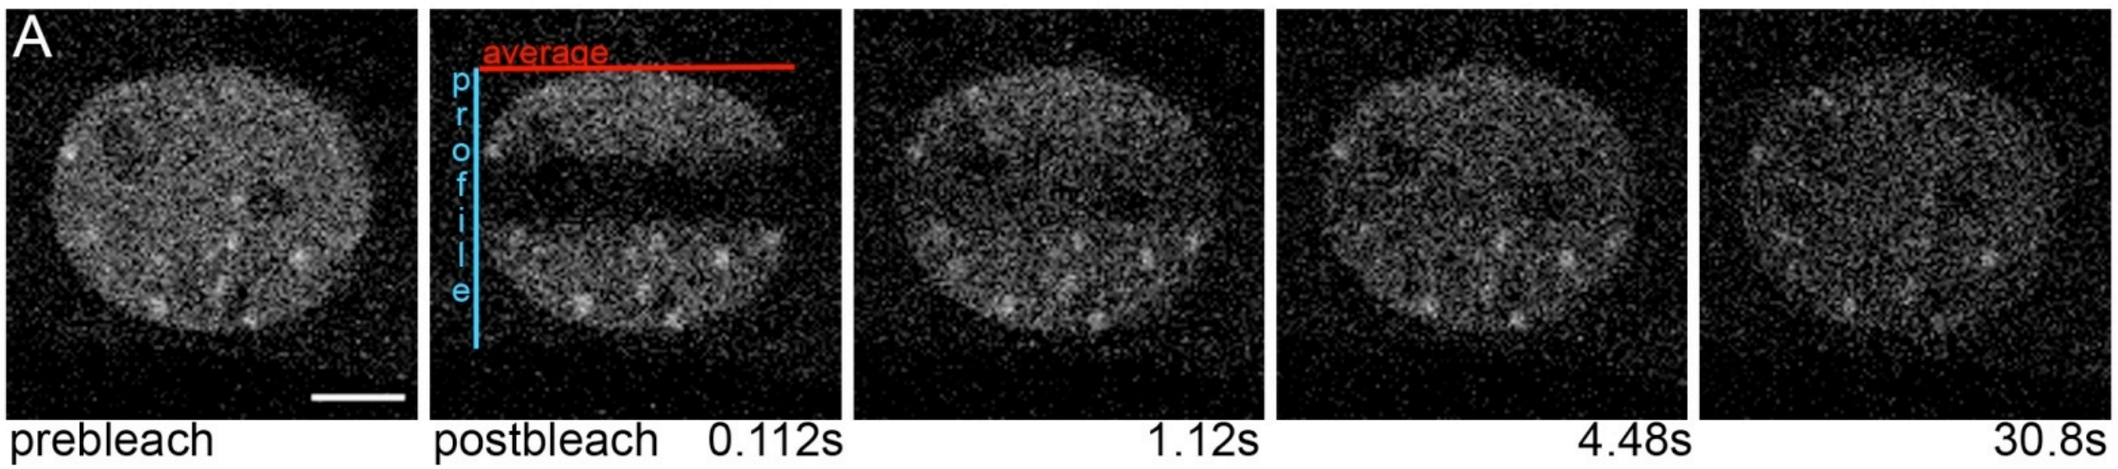


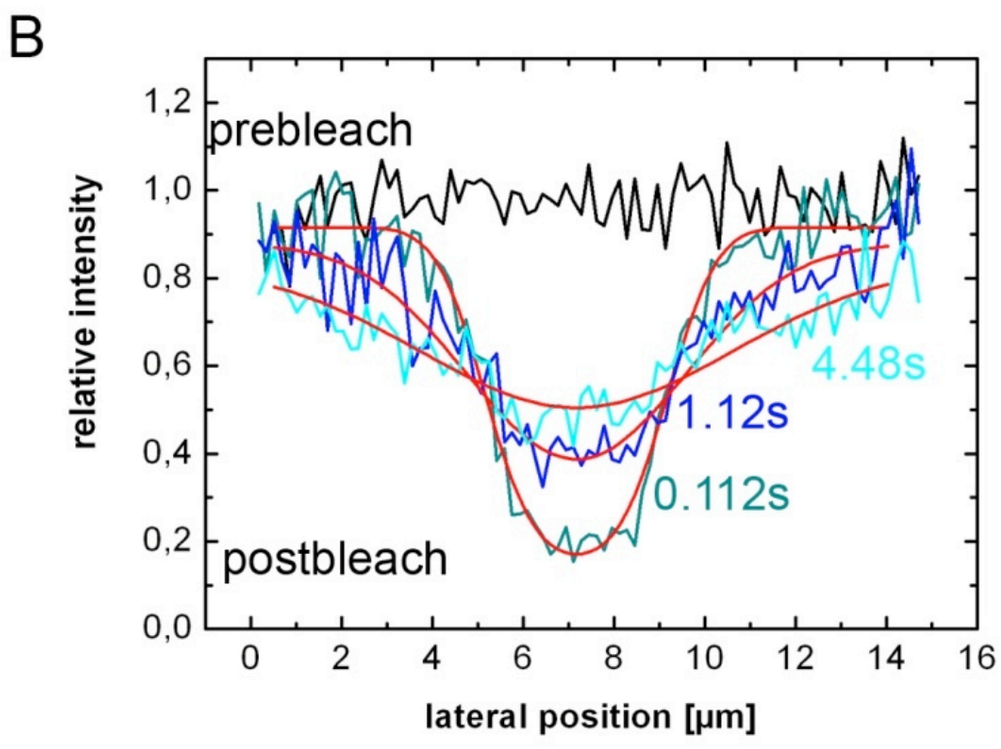


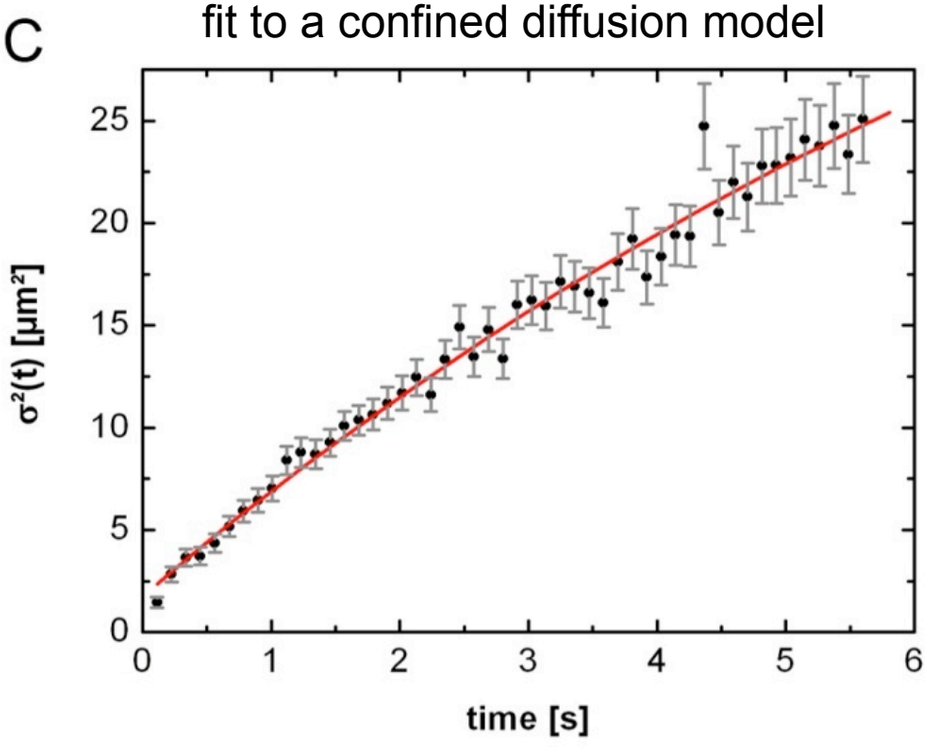


diffusion-reaction analysis (Sprague & McNally 2004, *Biophys. J.* **86**, 3473) yields k_{off} = 0.15 ± 0.07 s^{-1} in heterochromatin

FRAP profile analysis yields an effective nuclear diffusion coefficient of D_{eff} = 1.4 µm²·s^{-1} of HP1 (10 µm and second scale)







Diffusion versus binding in FRAP profile analysis

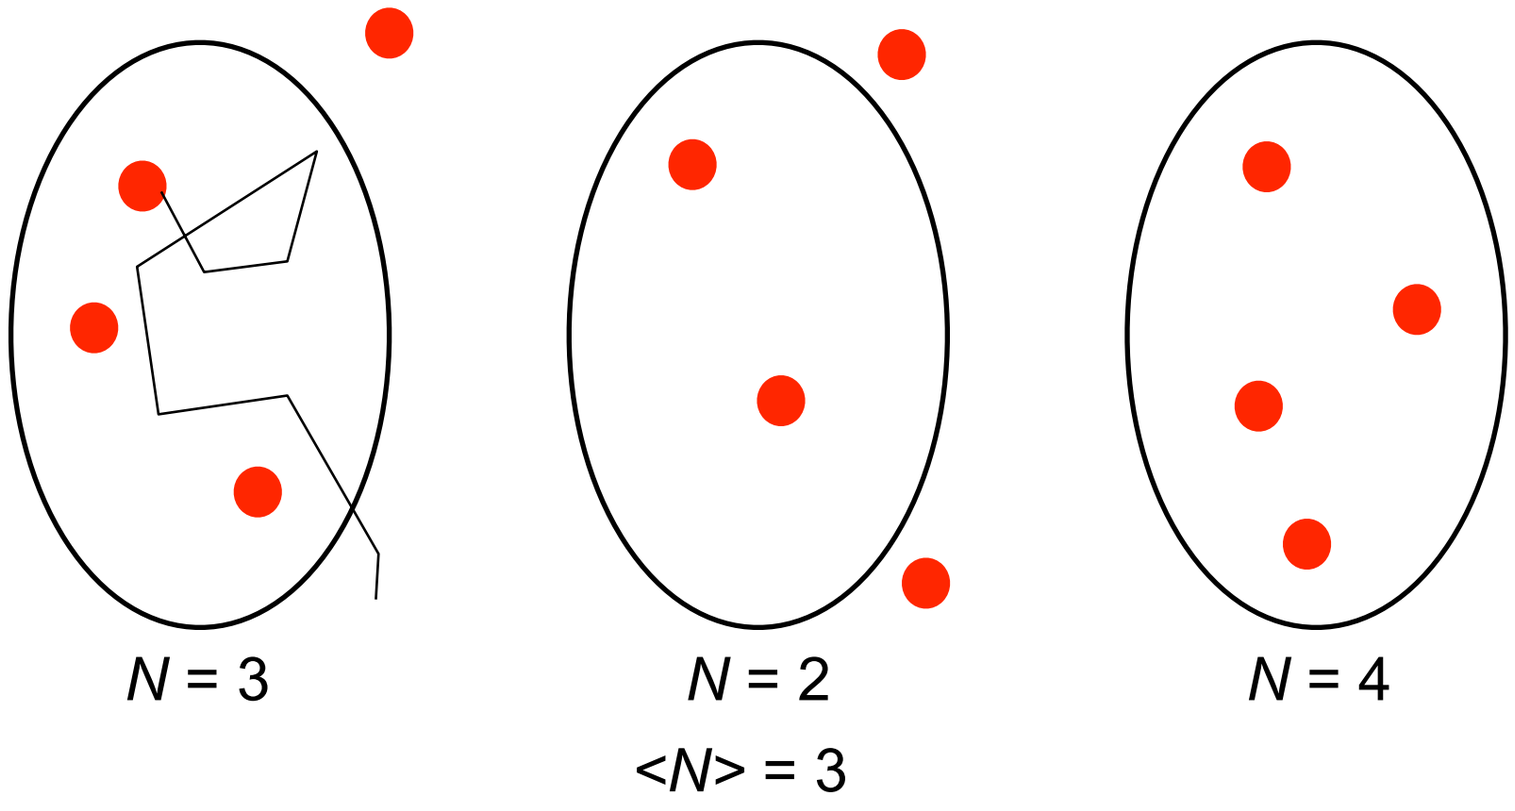
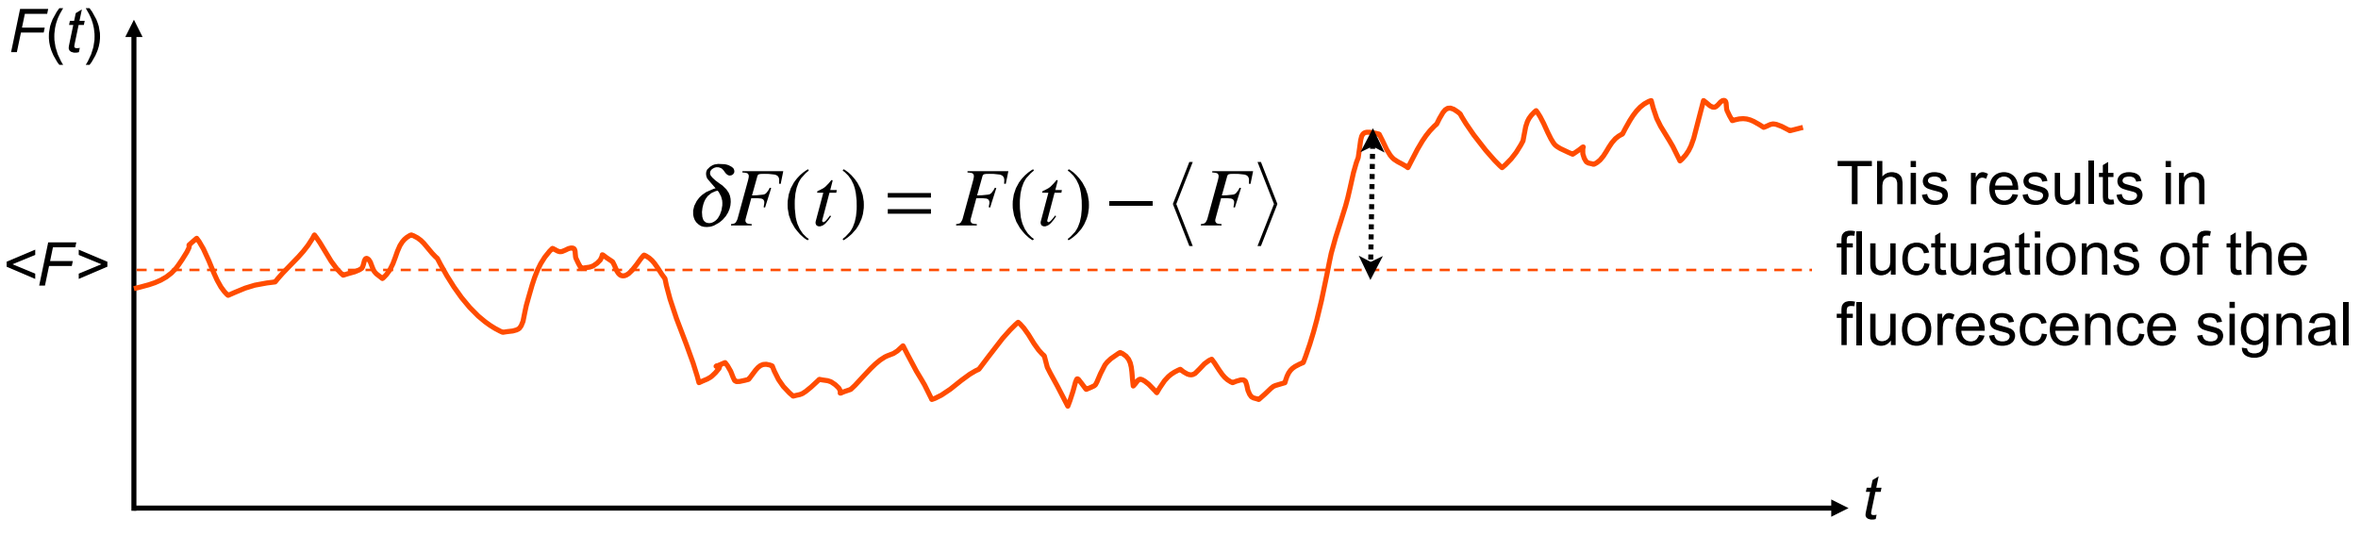
Fluorescence correlation spectroscopy

The concept: measuring number fluctuations of fluorescent particles in the focus



Diffusion induces fluctuations of the number of molecules

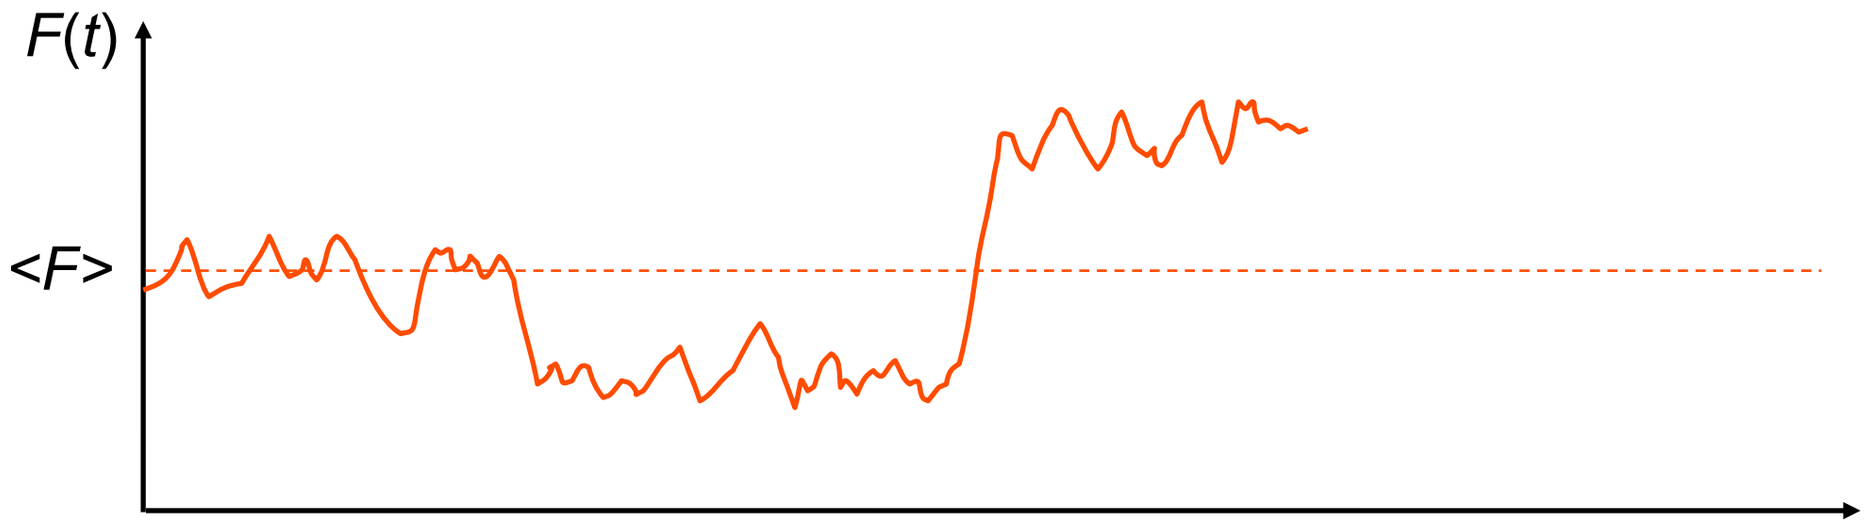


This results in fluctuations of the fluorescence signal

Fluctuations of the particle number of a 1 nM rhodamine solution in dependence of the observation volume

Size [mm]	Volume [l]	particles	ΔN	ΔN/N [%]
10	10^{-3}	$6.023 \cdot 10^{11}$	776080	0.00013
1	10^{-6}	$6.023 \cdot 10^{8}$	24541	0.0041
0.1	10^{-9}	$6.023 \cdot 10^{5}$	776	0.129
0.01	10^{-12}	602.3	24.5	4.075
0.001	10^{-15}	0.6023	0.776	128.9

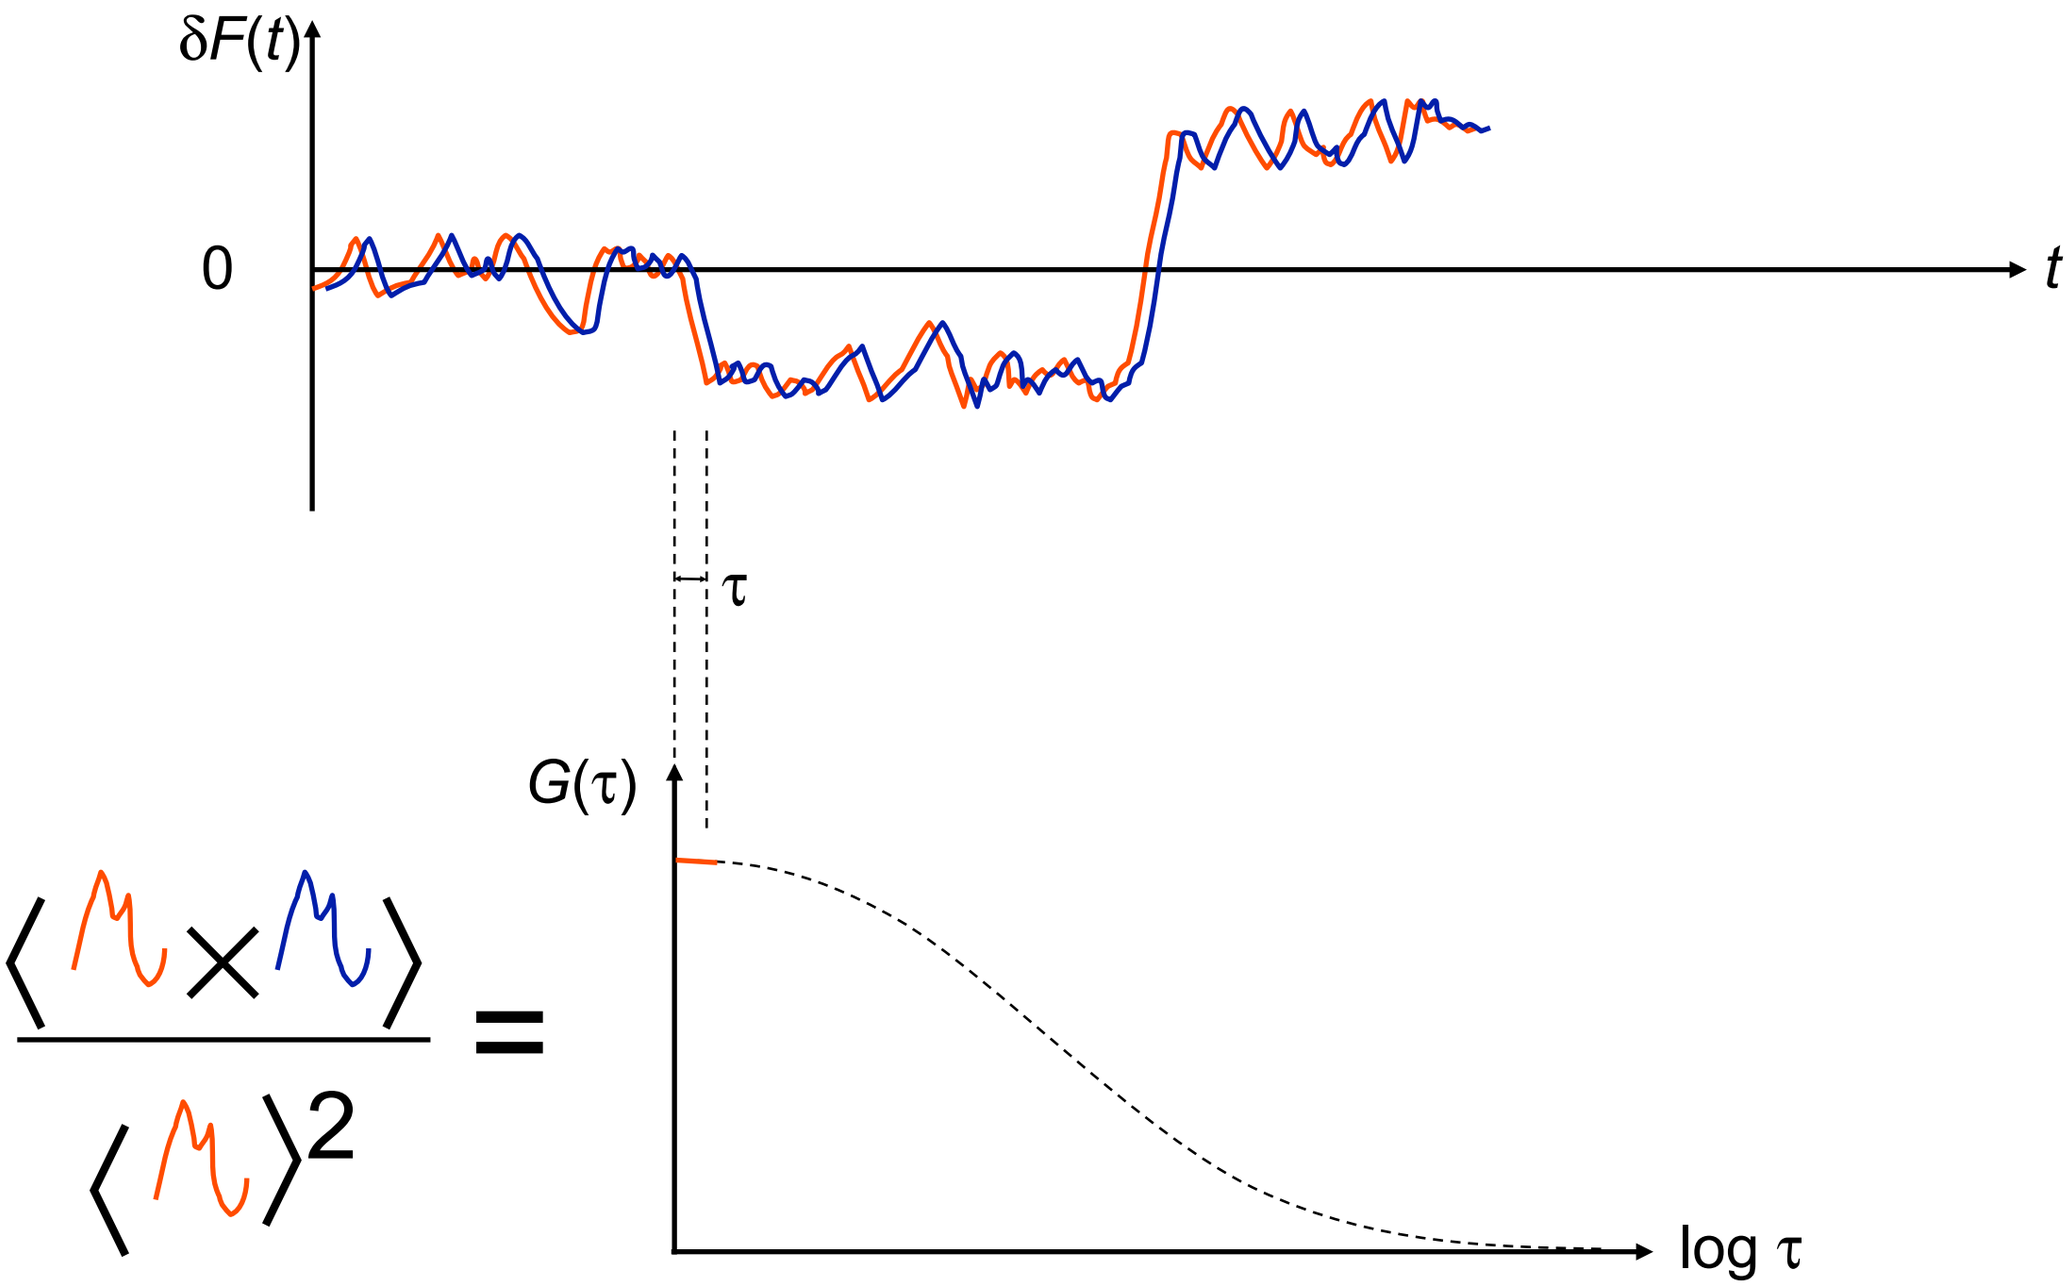
FCS data analysis



We want to know:

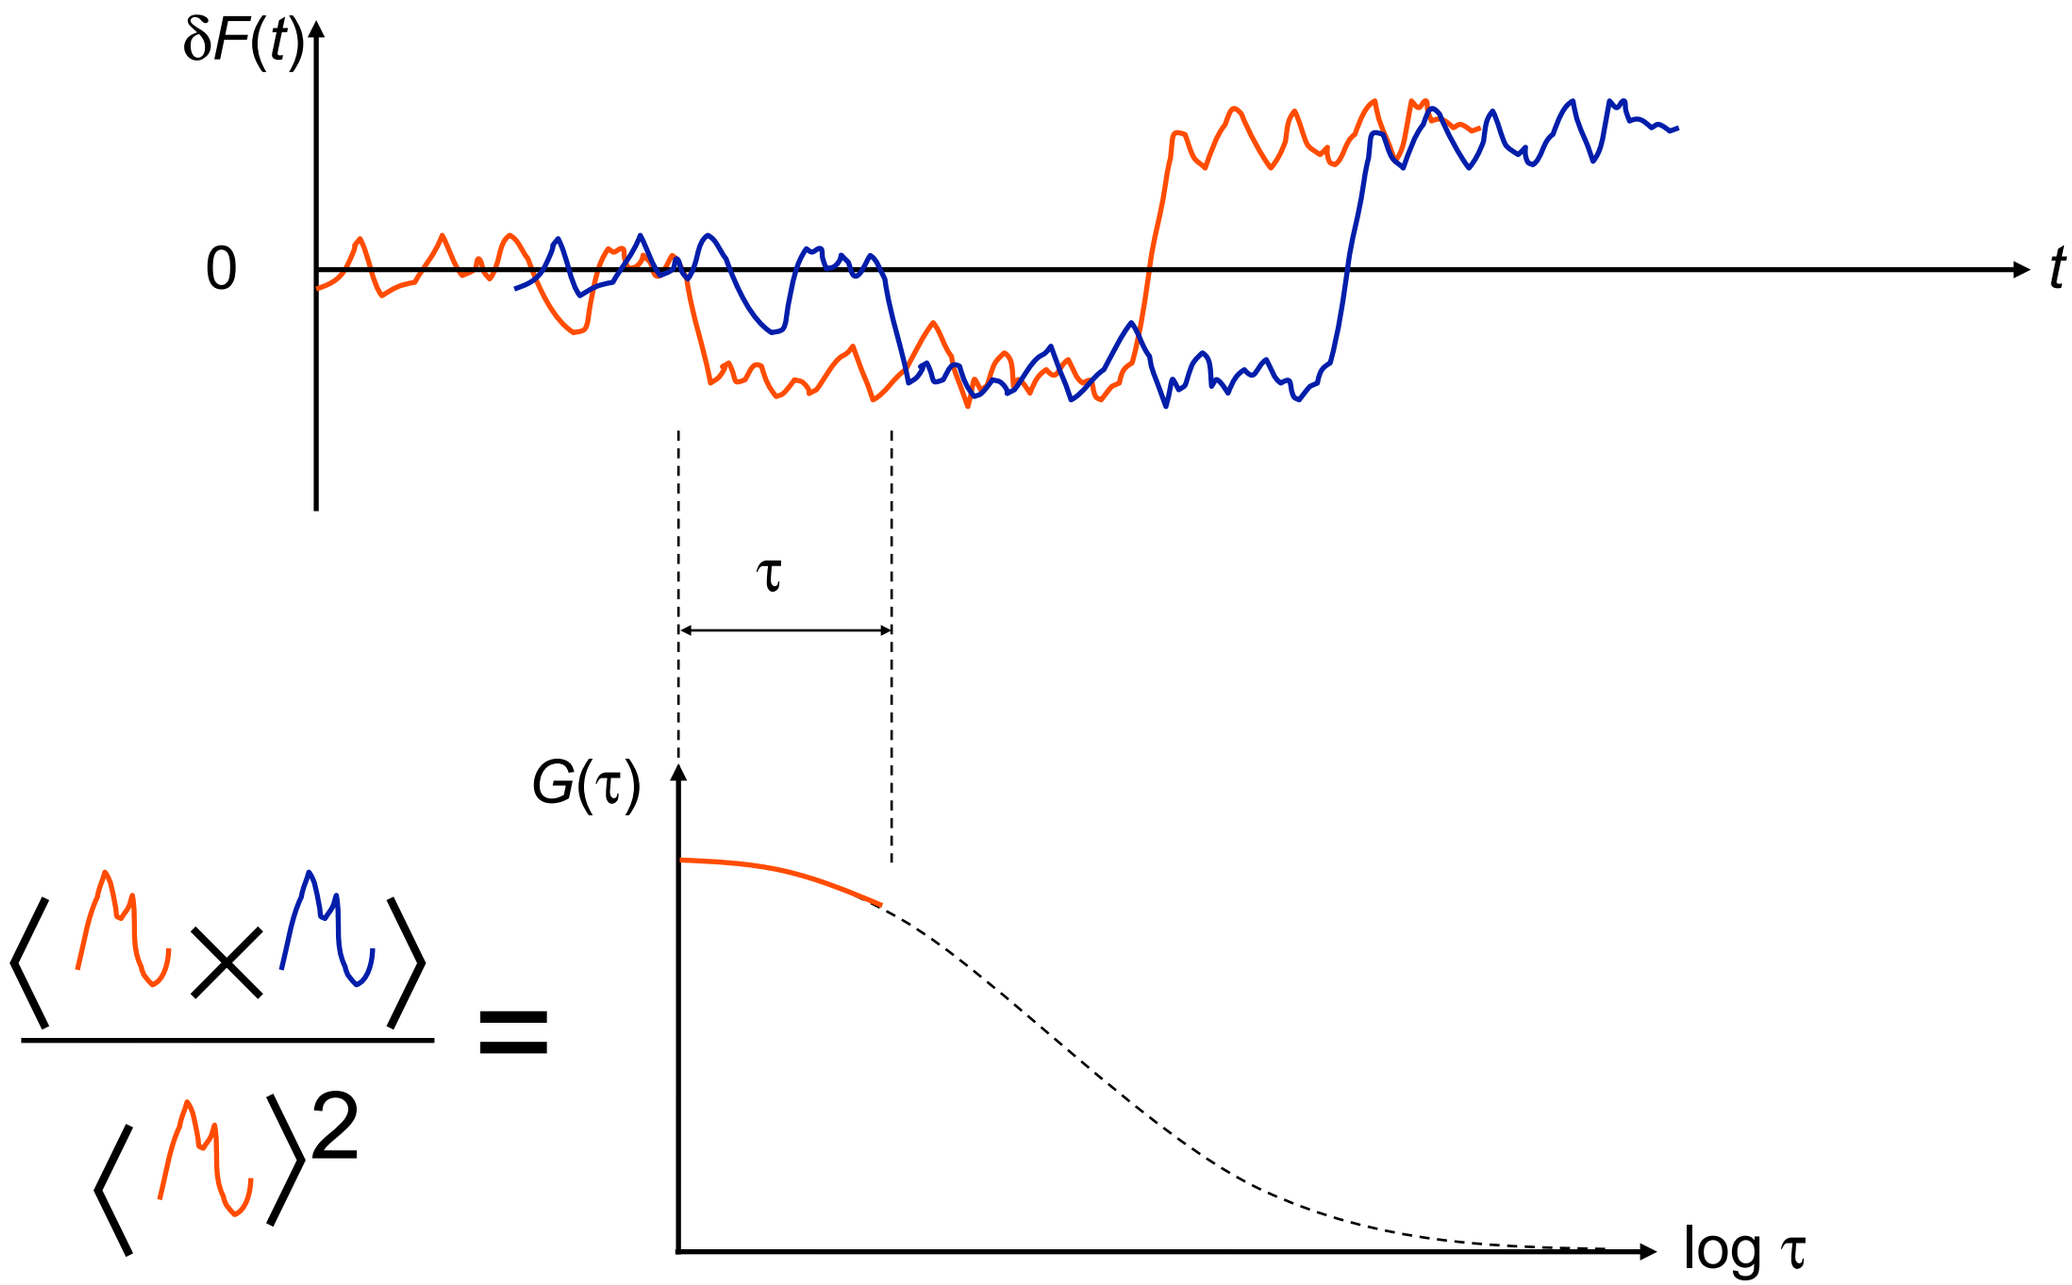
- the average number of molecules in the focus ⇒ concentration
- the dwell time in the focus ⇒ diffusion coefficient

The concept: autocorrelation analysis



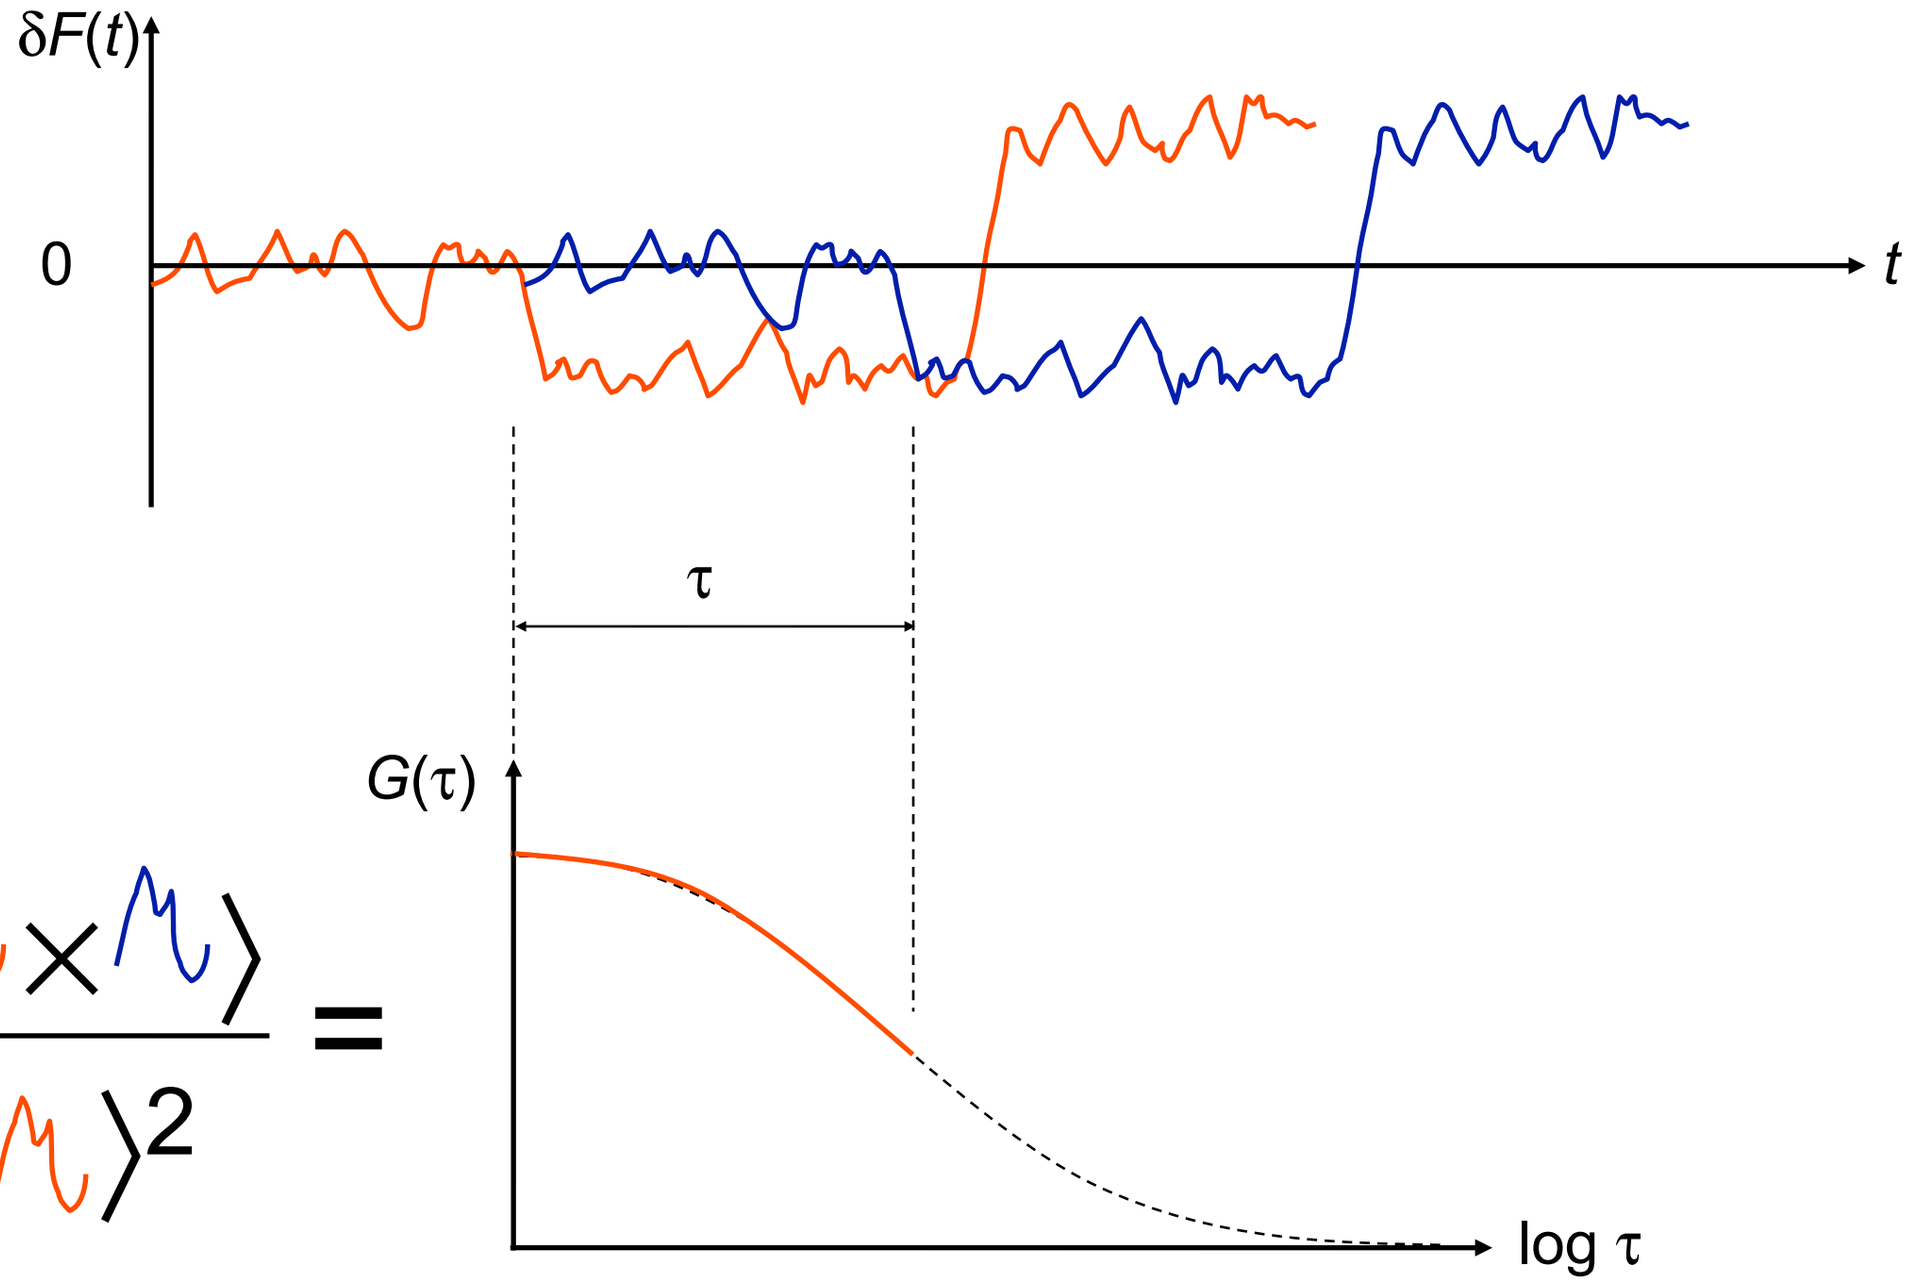
$$\frac{\langle \sim \times \sim \rangle}{\langle \sim \rangle^2} =$$

The concept: autocorrelation analysis



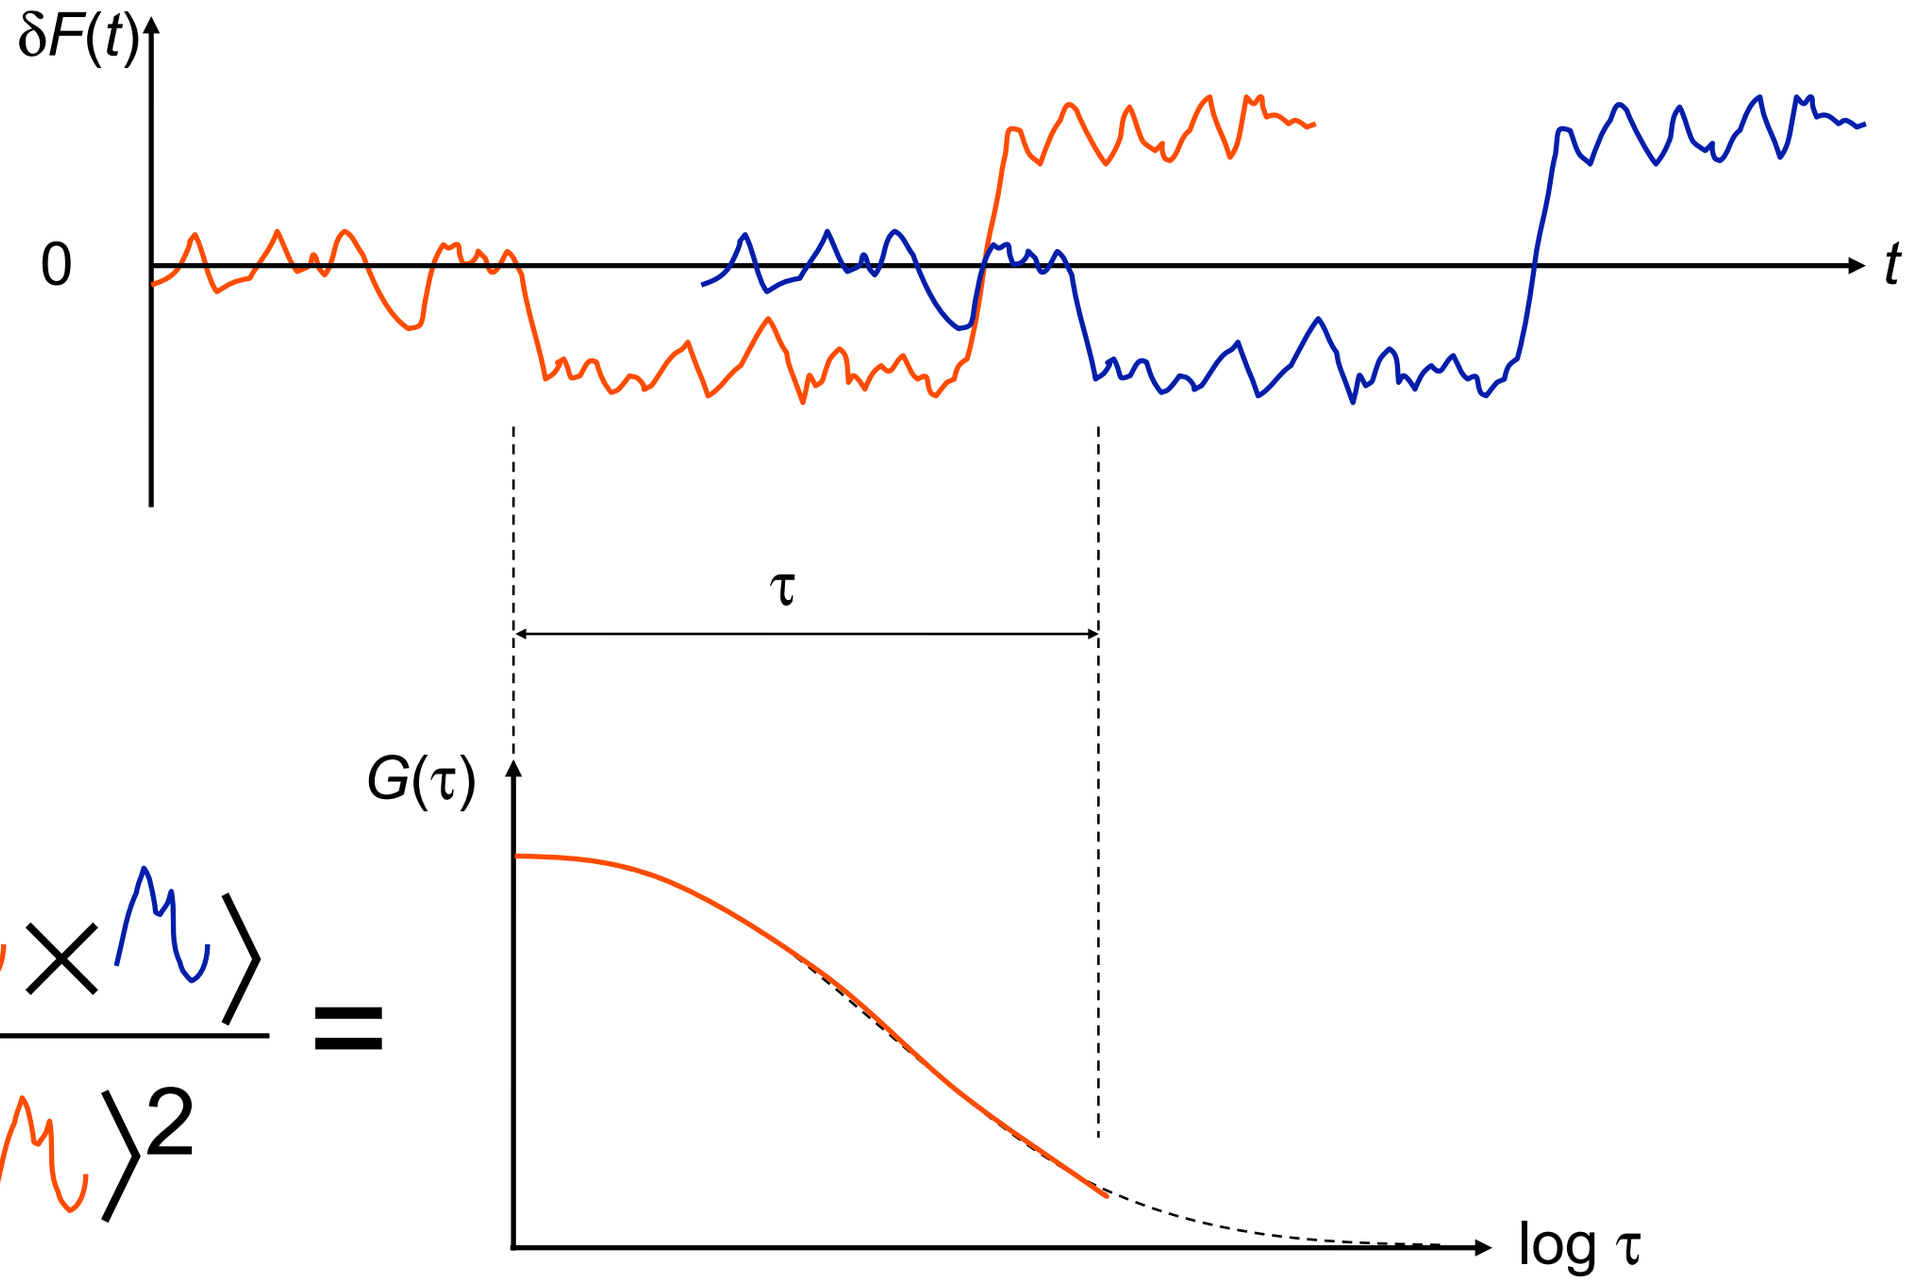
$$\frac{\langle \sim \times \sim \rangle}{\langle \sim \rangle^2} =$$

The concept: autocorrelation analysis



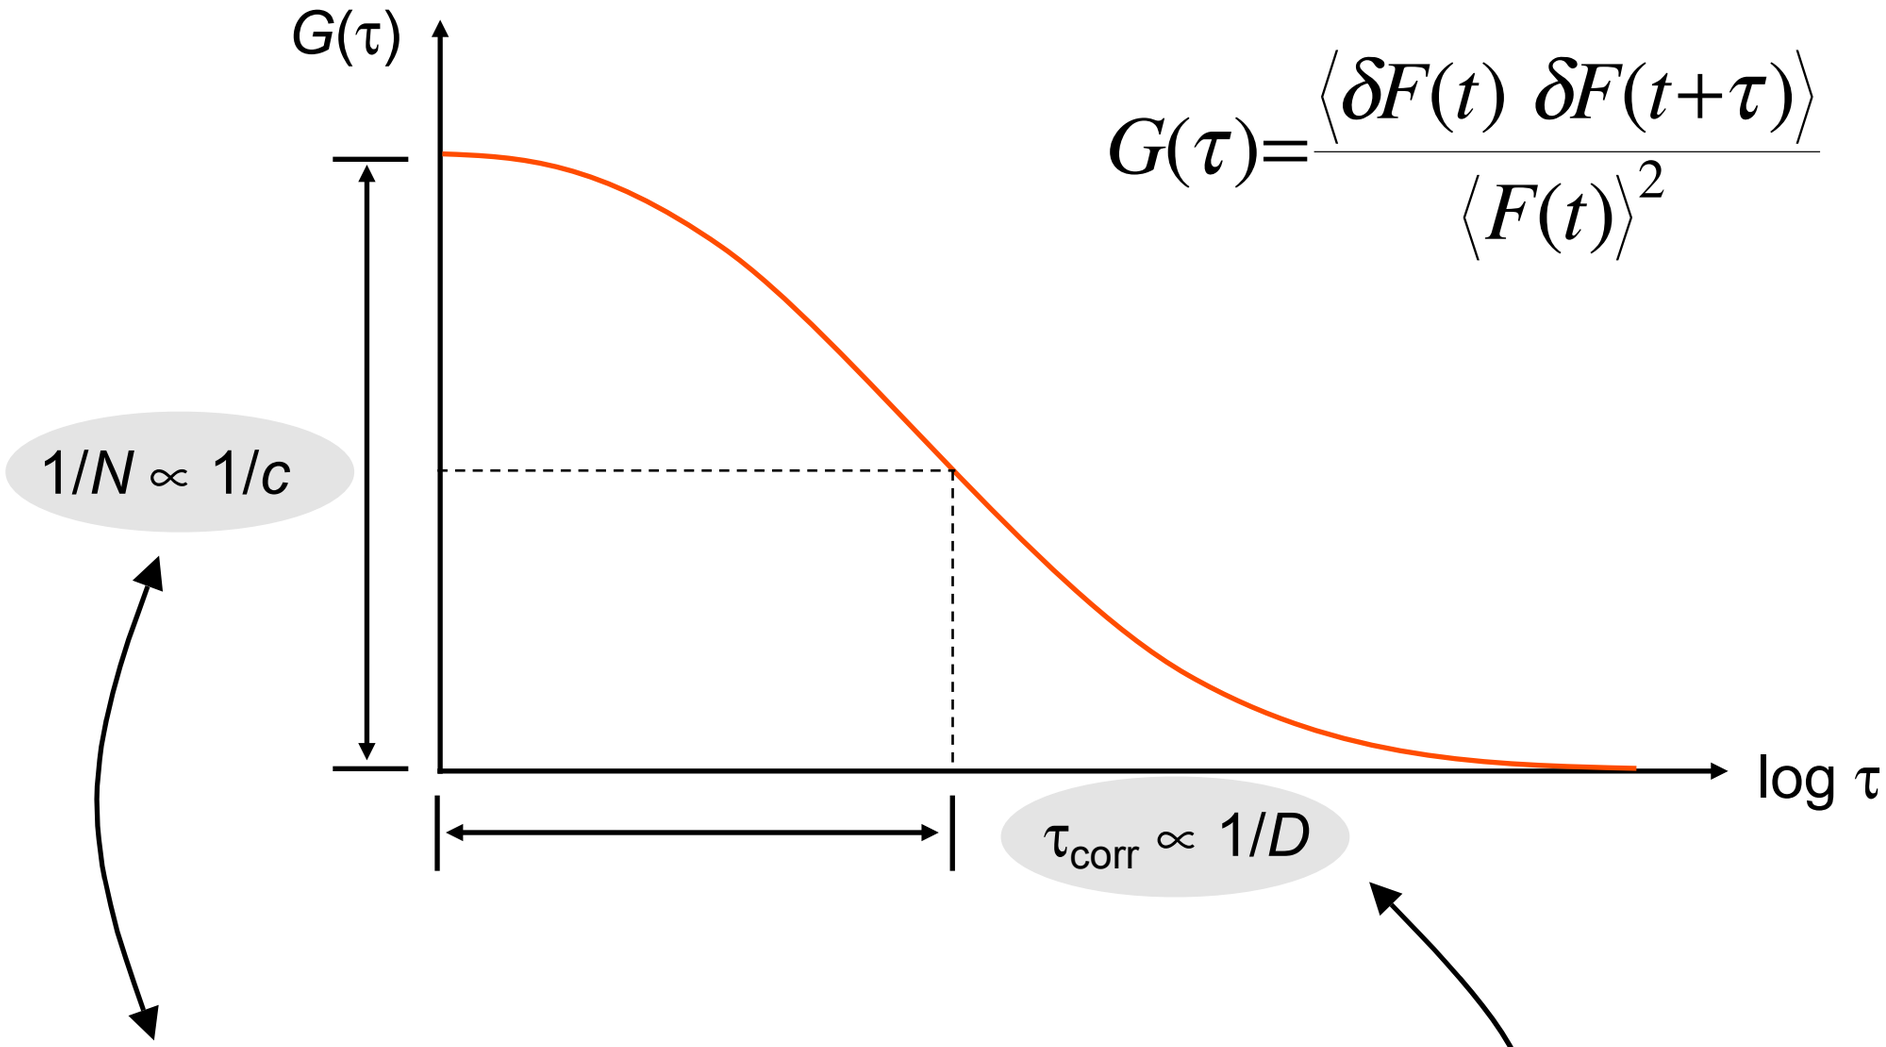
$$\frac{\langle \sim \times \sim \rangle}{\langle \sim \rangle^2} =$$

The concept: autocorrelation analysis



$$\frac{\langle \sim \times \sim \rangle}{\langle \sim \rangle^2} =$$

Results from FCS experiments



$$G(\tau)=\frac{\langle \delta F(t)\ \delta F(t+\tau)\rangle}{\langle F(t)\rangle^2}$$

- variance of fluctuations ⇒ concentration
- length of fluctuations ⇒ diffusion coefficient

Theoretical approach - formulas

Properties of the optical system

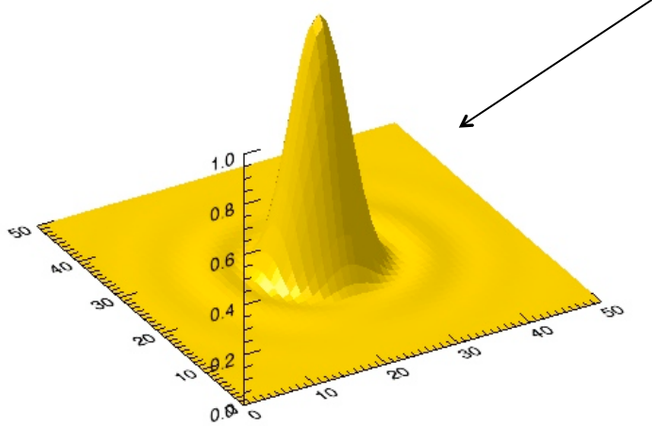
FCS – correlation function for free diffusion in 3D

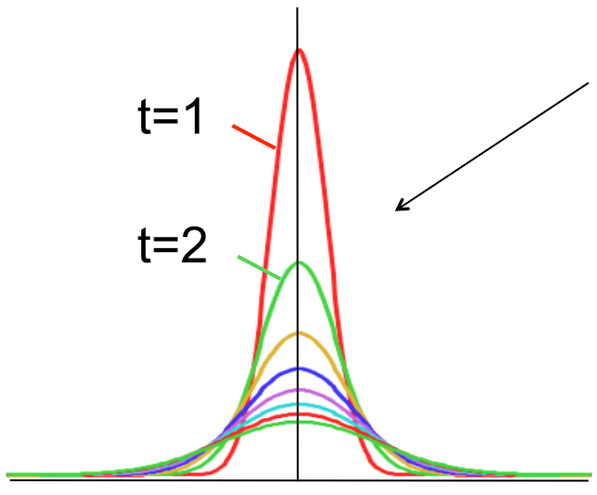
The correlation function $G(\tau)$ gives the probability to detect a particle at time t **and** at time $t + \tau$

detection efficiency



That's how a 'point' in the confocal microscope looks like

$$\Psi_k(\mathbf{r}) = \exp\left(-2\frac{x^2+y^2}{w_0^2} - 2\frac{z^2}{z_0^2}\right)$$



That's how a diffusing molecule spreads out over time (in 1 dimension)

Green's function for free 3D diffusion

$$P(\mathbf{r}_1,\mathbf{r}_2,\tau) = (4\pi D\tau)^{-3/2}\exp\left(-\frac{(\mathbf{r}_2-\mathbf{r}_1)^2}{4D\tau}\right)$$

FCS – correlation function for free diffusion in 3D

Probability to detect a particle **before** and **after** it has diffused for **time** τ

definition of the correlation function

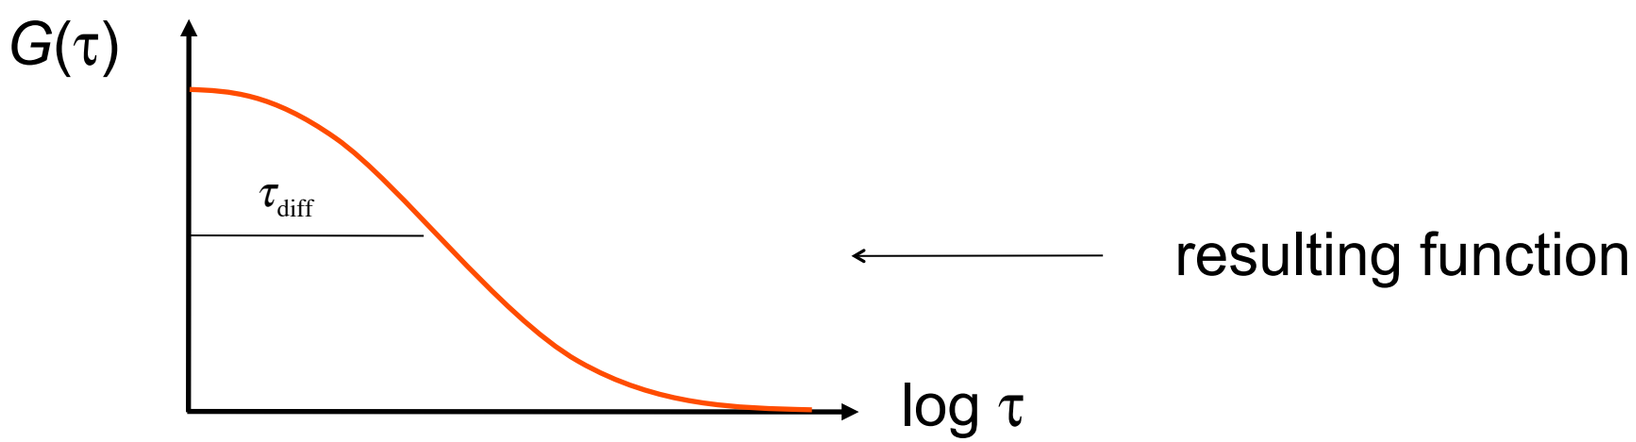
$$G_{kl}(\tau) = \frac{\int d^3 r_1 \int d^3 r_2 \Psi_k(\mathbf{r}_1) P(\mathbf{r}_1, \mathbf{r}_2, \tau) \Psi_l(\mathbf{r}_2)}{\int d^3 r \Psi_k(\mathbf{r}) \int d^3 r \Psi_l(\mathbf{r})}$$

correlation function

$$G_{kl}(\tau) = \frac{1}{cV_{\text{eff}}} \left(1 + \frac{\tau}{\tau_{\text{diff}}}\right)^{-1} \left(1 + \frac{1}{\kappa^2} \frac{\tau}{\tau_{\text{diff}}}\right)^{-1/2}$$

diffusion time, concentration, focal volume, structure parameter, focus radius

$$\tau_{\text{diff}} = \frac{w_0^2}{4D}, \quad V_{\text{eff}} = \pi^{3/2} w_0^2 z_0, \quad \kappa = \frac{z_0}{w_0}, \quad w_0^2 = \frac{w_k^2 + w_l^2}{2}$$

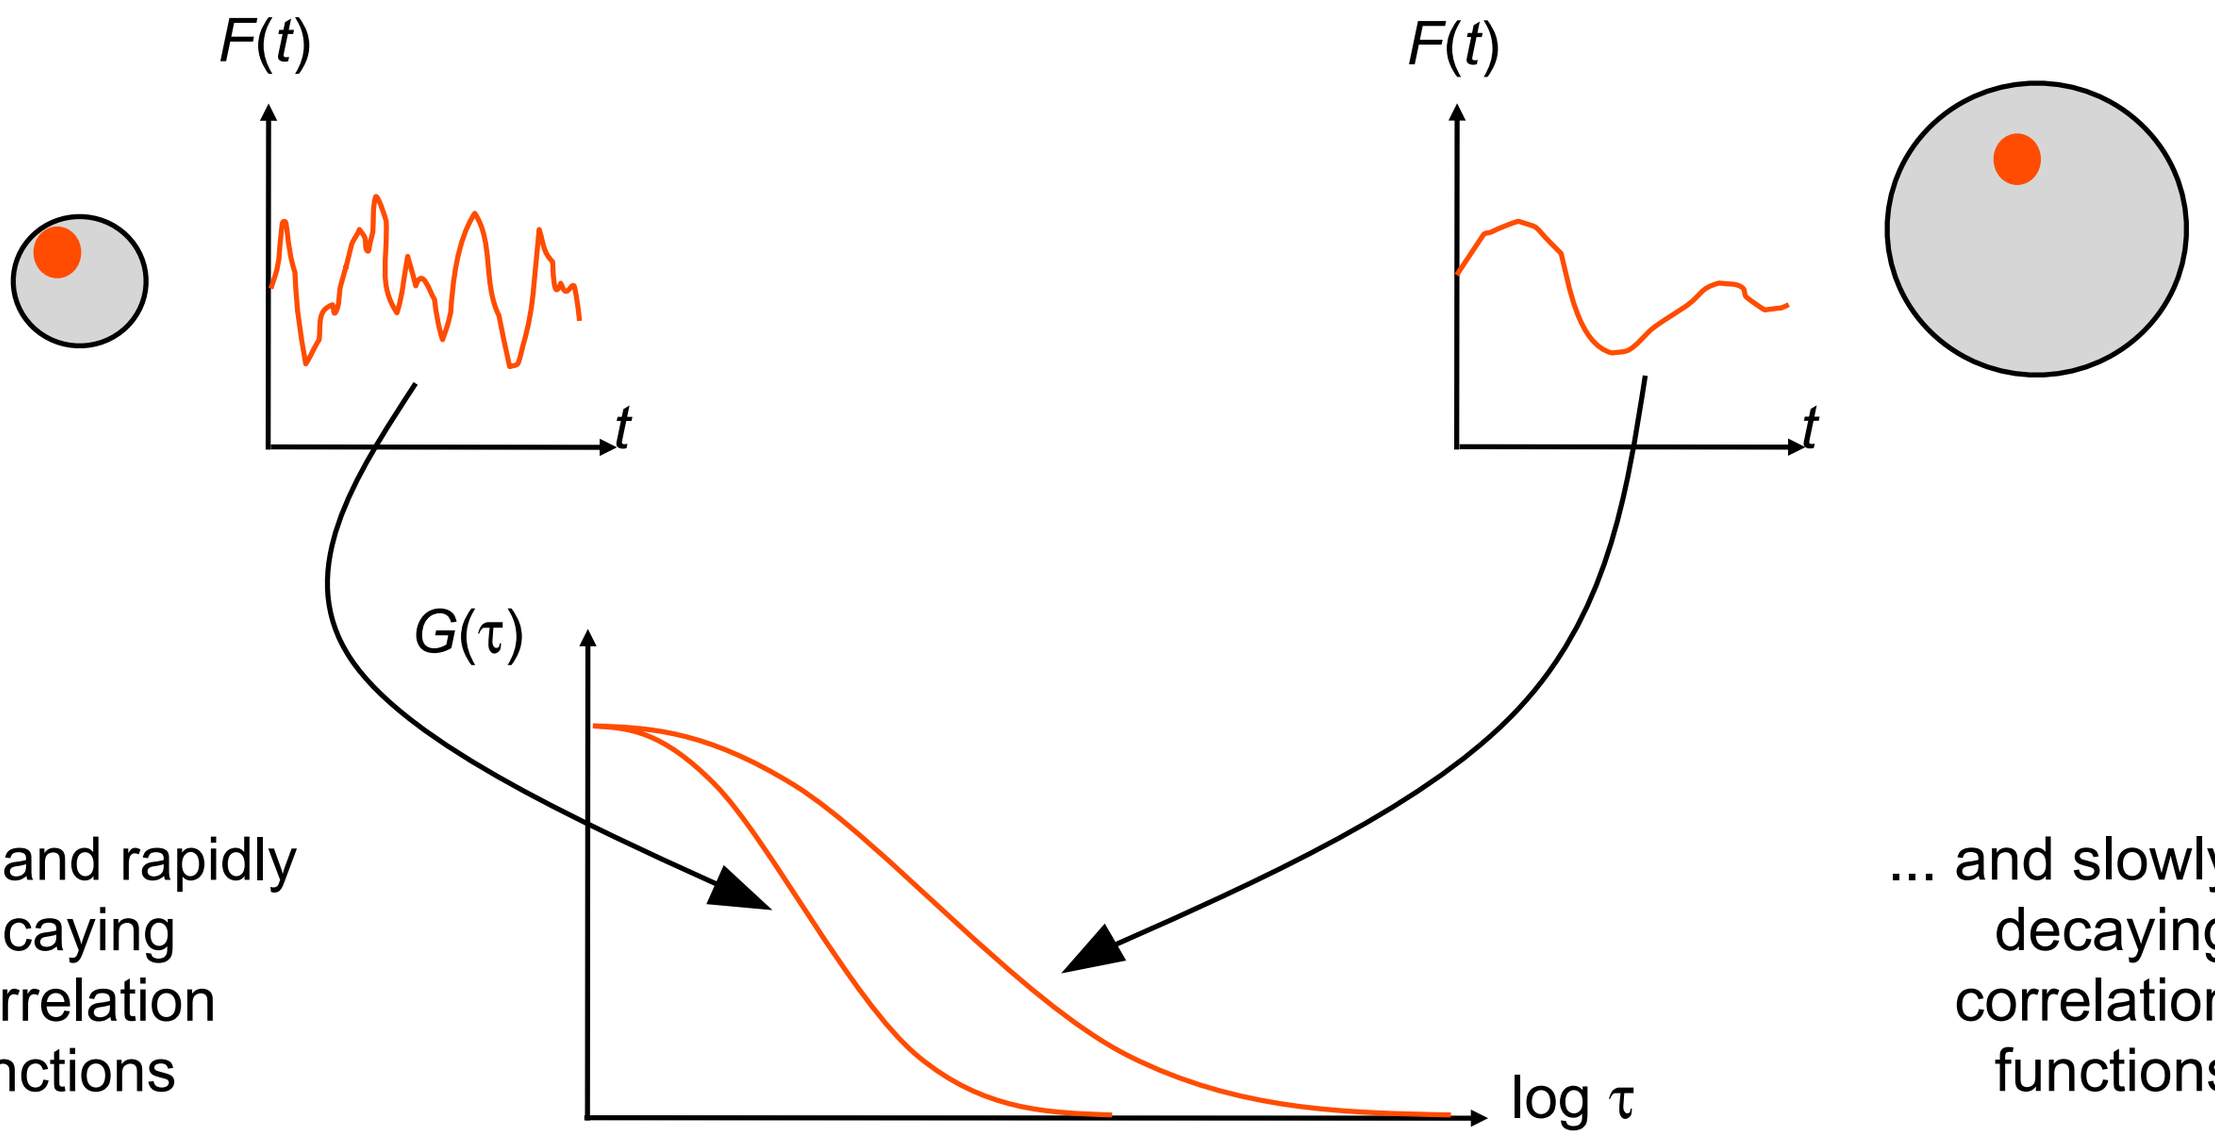


resulting function

Determining diffusion coefficients

small molecules generate short fluctuations...

larger complexes generate longer fluctuations...



... and rapidly decaying correlation functions

... and slowly decaying correlation functions
